

# 1

React JS

# Front End Applications Development

# Brief history of Web Applications

- Initially: static HTML files only with HTML forms for input
- Common Gateway Interface (CGI)
  - Certain URLs map to executable programs that generate web page
  - Program exits after Web page complete
  - Introduced the notion of stateless servers: each request independent, no state carried over from previous requests. (Made scale-out architectures easier)
  - Perl typically used for writing CGI programs

## First-generation web app frameworks

Examples: (PHP, ASP.net, Java servlets)

- Incorporate language runtime system directly into Web server
- **Templates:** mix code and HTML - HTML/CSS describes view
- Web-specific library packages:
  - URL handling
  - HTML generation
  - Sessions
  - Interfacing to databases

## Second-generation frameworks

Examples: (Ruby on Rails, Django):

- **Model-view-controller**: stylized decomposition of applications
- Object-relational mapping (**ORM**): simplify the use of databases (make database tables and rows appear as classes and objects)
  - Easier fetching of dynamic data

## Third-generation frameworks

### Example: Angular

- JavaScript frameworks running in browser - More app-like web apps
  - Interactive, quick responding applications - Don't need server round-trip
- Frameworks not dependent on particular server-side capabilities
  - Node.js - Server side JavaScript
  - No-SQL database (e.g. MongoDB)
- Many of the concepts of previous generations carry forward
  - Model-view-controller
  - Templates - HTML/CSS view description

# Model-View-Controller (MVC) Pattern

- **Model:** manages the application's data
    - JavaScript objects. Photo App: User names, pictures, comments, etc.
  - **View:** what the web page looks like
    - HTML/CSS. Photo App: View Users, View photo with comments
  - **Controller:** fetch models and control view, handle user interactions
    - JavaScript code. Photo App: DOM event handlers, web server communication
- MVC pattern been around since the late 1970's
- Originally conceived in the Smalltalk project at Xerox PARC

- Web App: Ultimately need to generate HTML and CSS
- **Templates** are commonly used technique. Basic ideas:
  - Write HTML document containing parts of the page that are always the same.
  - Add bits of code that generate the parts that are computed for each page.
  - The template is expanded by executing code snippets, substituting the results into the document.
- Benefits of templates (Compare with direct JavaScript to DOM programming)
  - Easy to visualize HTML structure
  - Easy to see how dynamic data fits in
  - Can do either on server or browser

## AngularJS view template (HTML/CSS)

```
...
<body>
  <div class="greetings">
    Hello {{models.user.firstName}},
  </div>
  <div class="photocounts">
    You have {{models.photos.count}} photos to review.
  </div>
</body>
```

Angular has rich templating language (loops, conditions, subroutines, etc.). Later...

- Third-generation: JavaScript running in browser Responsibilities:
- Connect models and views
  - Server communication: Fetch models, push updates
- Control view templates
  - Manage the view templates being shown
- Handle user interactions
  - Buttons, menus, and other interactive widgets

## AngularJS controller (JavaScript function)

```
function userGreetingView ($scope, $modelService) {  
  $scope.models = {};  
  
  $scope.models.users = $modelService.fetch("users");  
  $scope.models.photos = $modelService.fetch("photos");  
  
  $scope.okPushed = function okPushed() {  
    // Code for ok button pushing  
  }  
}
```

Angular creates \$scope and calls controller function called when view is instantiated

## Model Data

- All non-static information needed by the view templates or controllers
- Traditionally tied to application's database schema
  - Object Relational Mapping (ORM) - A model is a table row
- Web application's model data needs are specified by the view designers But need to be persisted by the database
- Conflict: Database Schemas don't like changing frequently but web application model data might (e.g. user will like this view better if we add ... and lose ...)

## Angular doesn't specify model data (JavaScript objs)

- Angular provides support for fetching data from a web server
  - REST APIs
  - JSON frequently used

On Server:

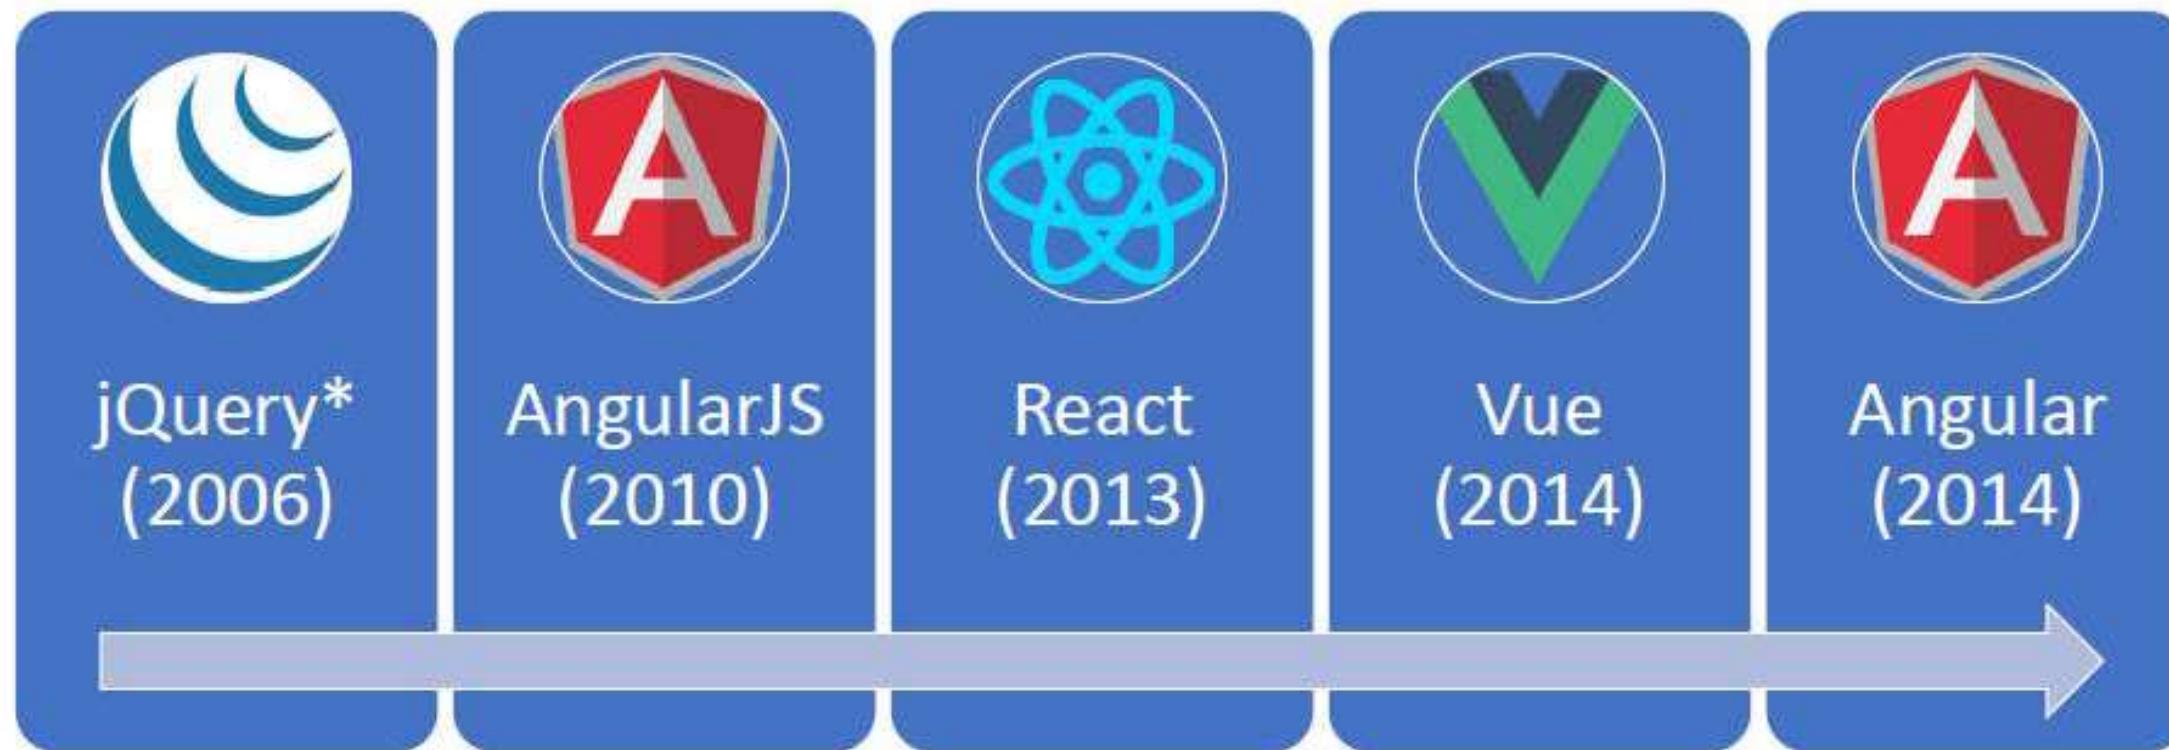

- Mongoose's Object Definition Language (ODL) has "models"

```
var userSchema = new Schema({  
    firstName: String,  
    lastName: String,  
});  
var User = mongoose.model('User', userSchema);
```

## Fourth-generation frameworks

Examples: React.js, Vue.js, Angular(v2)

- Many of the concepts of previous generations carry forward
  - JavaScript in browser
  - Model-view-controllers
  - Templates
- Focus on JavaScript components rather than pages/HTML
  - Views apps as assembled reusable components rather than pages.
  - Software engineering focus: modular design, reusable components, testability, etc.
- Virtual DOM
  - Render view into DOM-like data structure (not real DOM)
  - Benefits: Performance, Server-side rendering, Native apps

\* jQuery is more often considered a library than a framework

# Common tasks in front-end development

**App state**

Data definition, organization, and storage

**User actions**

Event handlers respond to user actions

**Templates**

Design and render HTML templates

**Routing**

Resolve URLs

**Data fetching**

Interact with server(s) through APIs and AJAX

**Every framework can be viewed as an attempt to say "the hardest part of writing a webapp is \$X, so here's some code to make that easier".**

Knockout.js is basically what you get when a dev says "the hardest part of writing a webapp is implementing two-way data binding", which you can tell because that's basically 90% of what the framework does.

Similarly, Backbone is the result of feeling like the hard parts are fetching and persisting models to a REST API, and client side routing; that's basically all it does. Figuring out how to turn your models into HTML is easy (apparently), but models are hard, so it helps you.

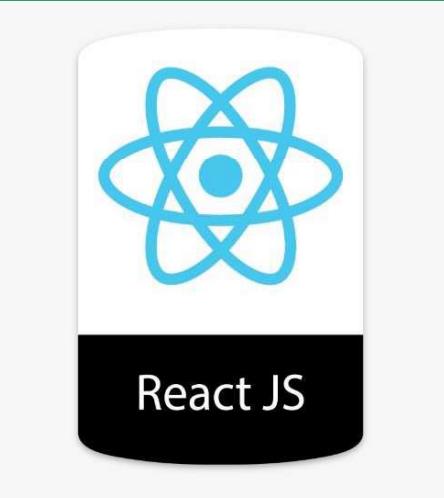

Cont ...

**Angular is what you get if you think the biggest problem with writing webapps is that Javascript isn't Java; Ember that it's not Ruby.** (I kid. But I'm less familiar with those frameworks.) And so on. Everyone has their own ideas of what's hard to solve.

**React + Redux is based on the idea that what's really hard with writing webapps is non-deterministic behaviour and unclear data flow.** And if you've worked on a large Knockout or Backbone project, you're probably inclined to agree.

Cont ...

- **Why do frameworks exist?**
  - Keep state out of the DOM
  - Higher-level abstractions
  - Code organization
- **Pros**
  - Common concepts that can be shared between apps and developers
  - Large communities, shared knowledge, documentation, bug fixes
  - Better app structure through tools and guidelines
- **Cons**
  - Learning curve
  - Minimum requirements for size
  - Setup and infrastructure

# Responsive Web Design

## Web App Challenges: Screen real estate

320x640

640x320

768x1024

768x1024

1920x1028

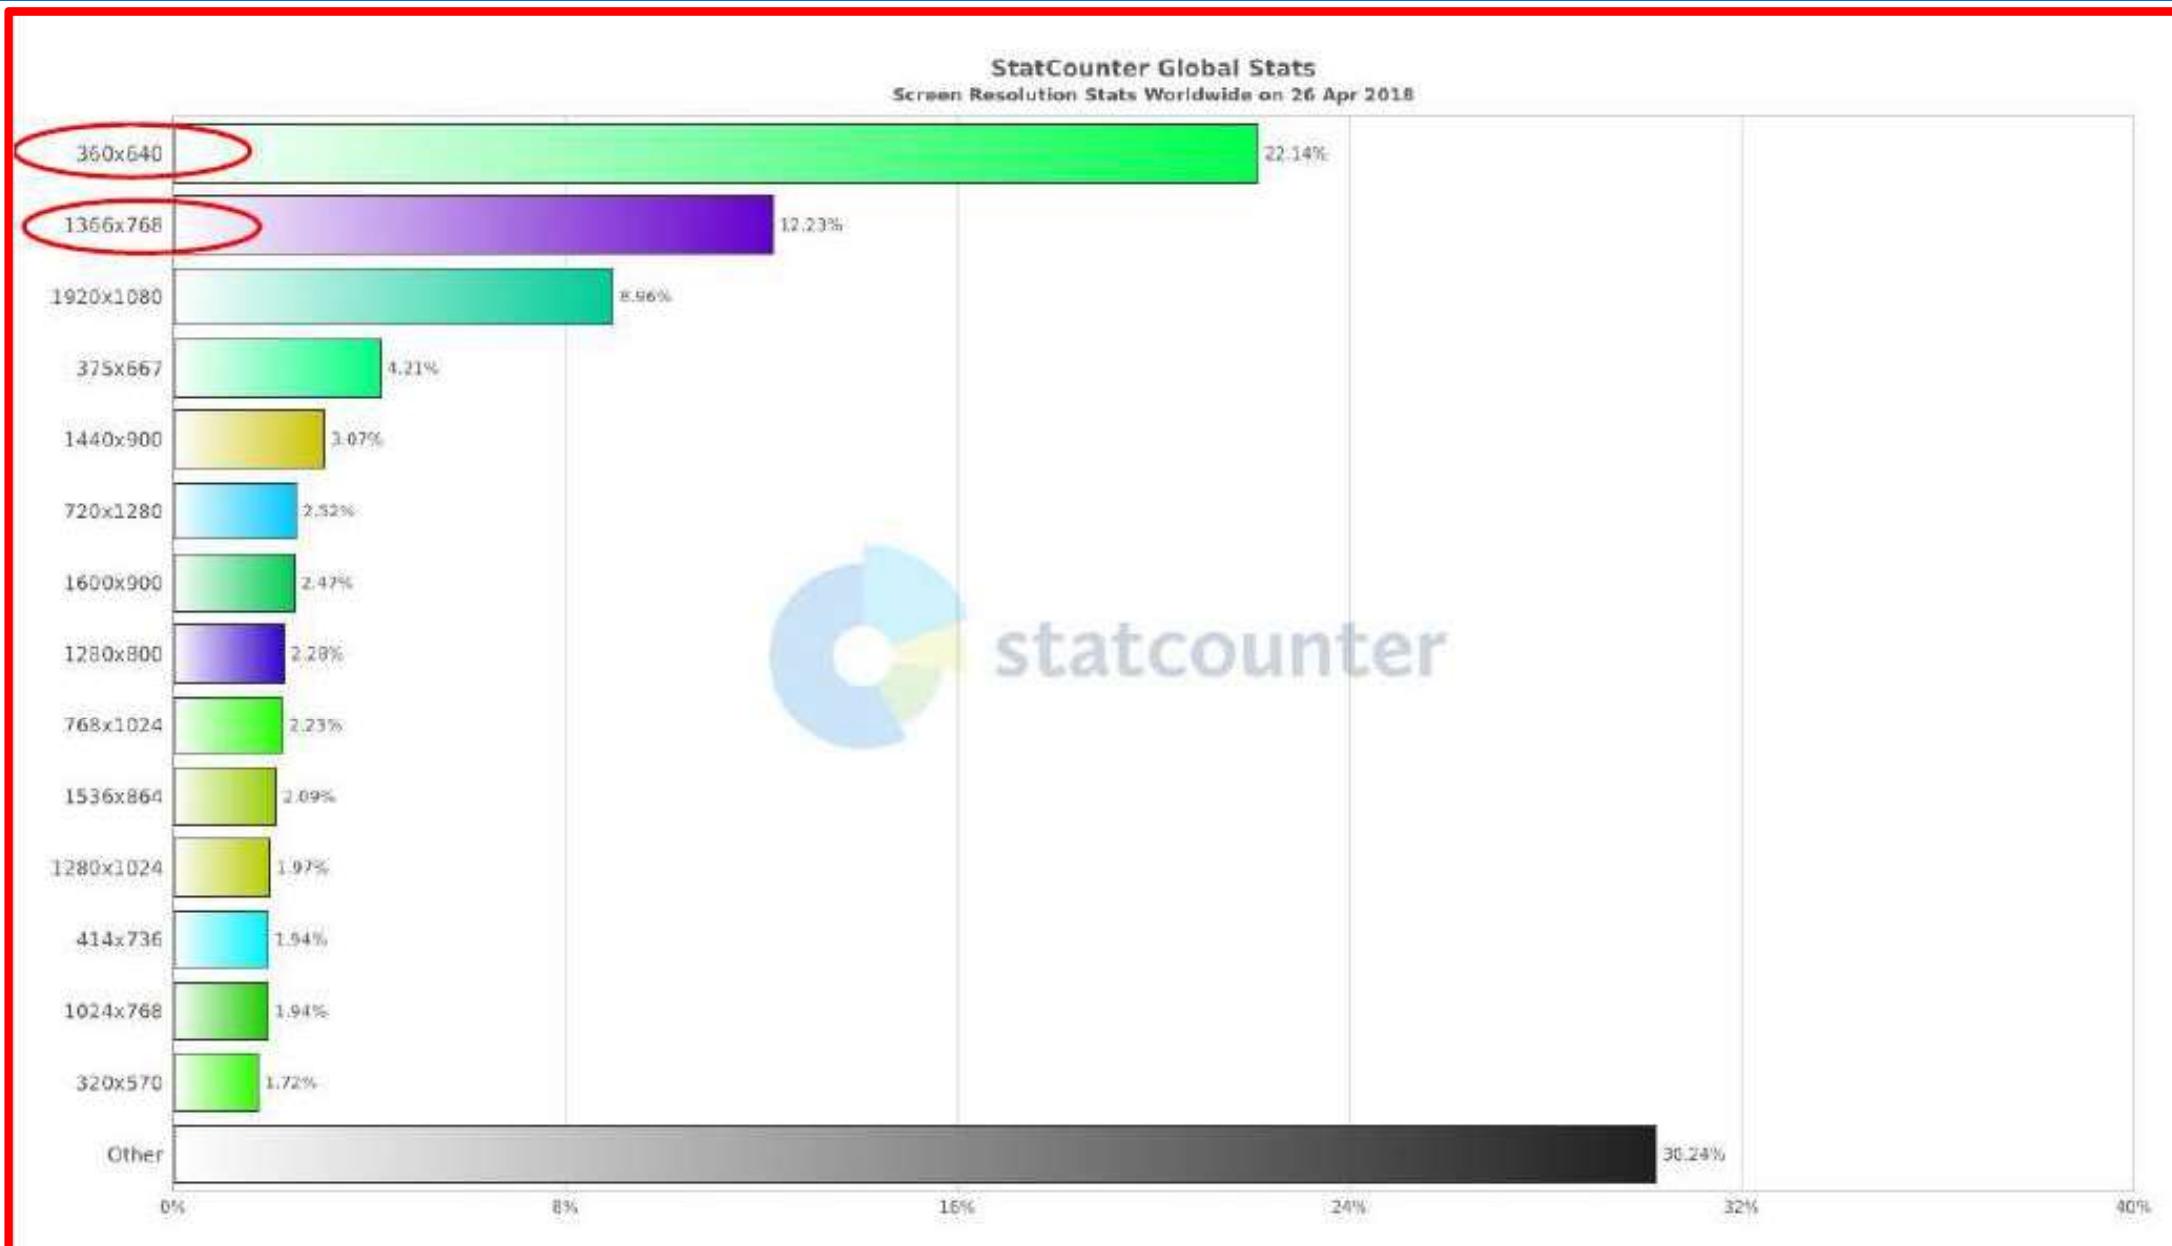

Cell Phones

Tablets

Desktops

- Do we need to build N versions of each web application?

# Statistics

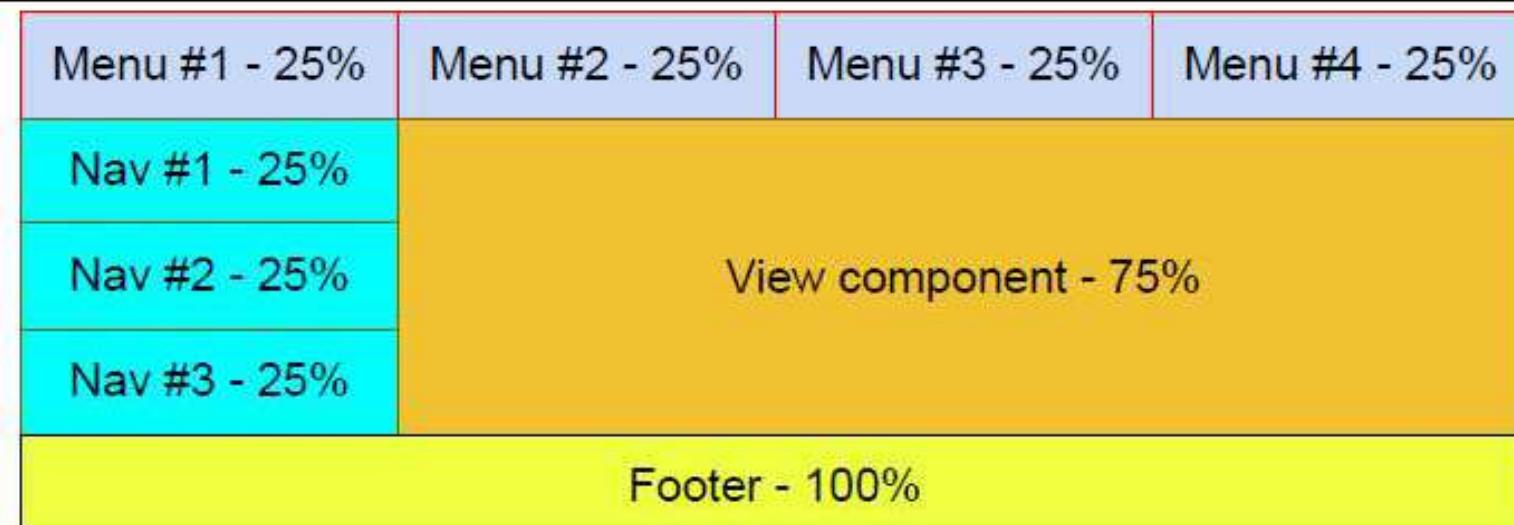

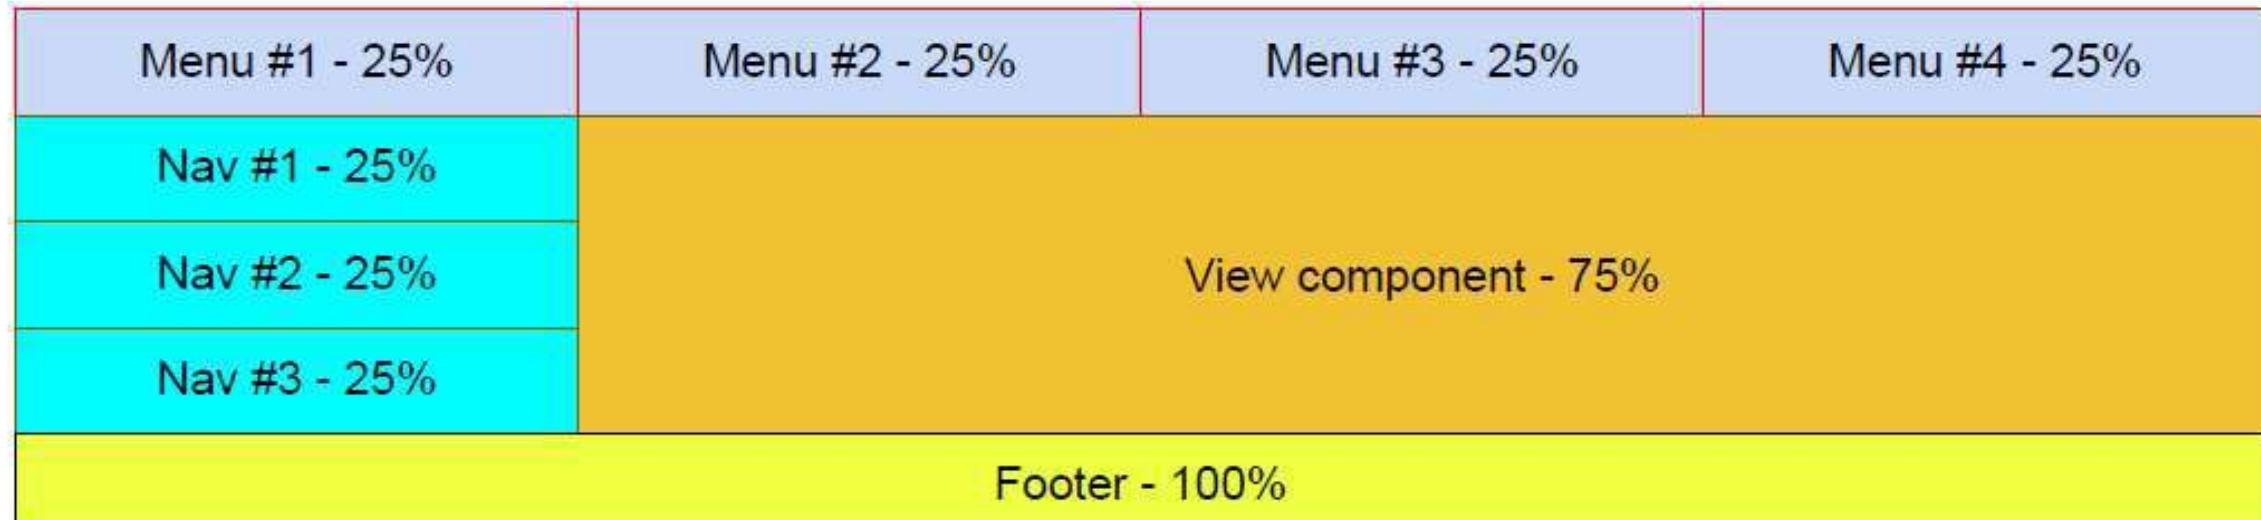

# Responsive Web Design

- Content is like water!
  - The web app should flow into and fill whatever device you have.
- Possible with CSS extensions:
  - Add grid layout system with relative (e.g. 50%) rather than absolute (e.g. 50pt) measures
    - Specify element packing into columns and rows
  - Add @media rules based on screen sizes
    - Switch layout based on screen size
  - Make images support relative sizes
    - Autoscale image and videos to fit in screen region

```
img { width: 100%; height: auto; }  
video { width: 100%; height: auto; }
```

# Example of Responsive Web Layout

# CSS Breakpoints

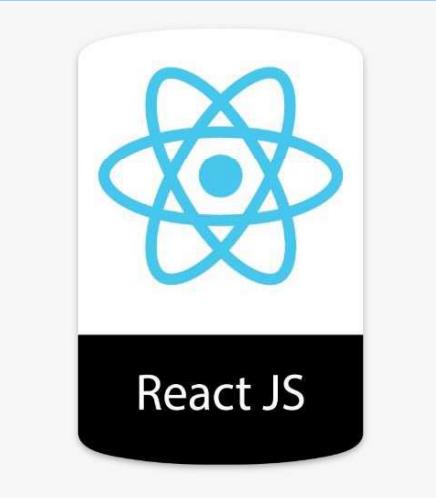

## CSS Rules:

```
@media only screen and (min-width: 768px) {  
    /* tablets and desktop layout */ }  
  
@media only screen and (max-width: 767px) {  
    /* phones */ }  
  
@media only screen and (max-width: 767px)  
and (orientation: portrait) {  
    /* portrait phones */ }
```

# Responsive implementation

- Build components to operate at different screen sizes and densities
  - Use relative rather than absolute
  - Specify sizes in device independent units
- Use CSS breakpoints to control layout and functionality
  - Layout alternatives
  - App functionality conditional on available screen real estate
- Mobile first popular
  - Expand a good mobile design to use more real estate

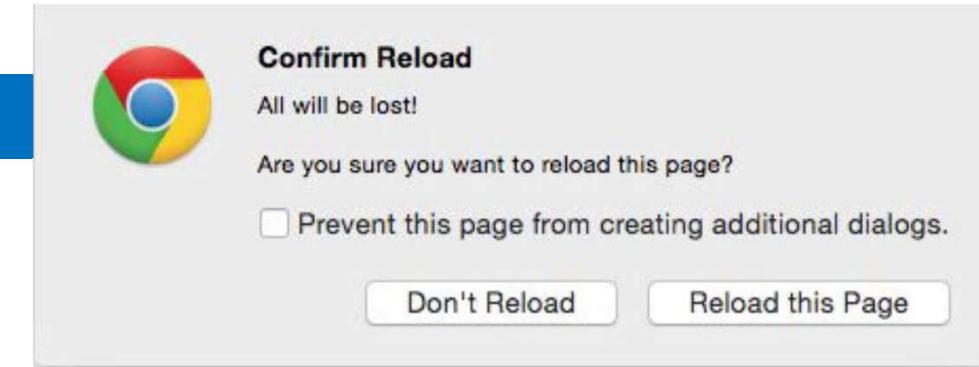

# Single Page Applications (SPA)

# Web Apps and Browsers

- Web apps run in browsers (by definition)
- Users are used to browsing in browsers
  - Browser maintains a history of URLs visited
    - Back button - Go back in history to previous URL
    - Forward button - Go forward in history to next URL
  - Can move to a different page
    - Typing into location bar or forward/back buttons
    - Selecting a bookmarked URL
    - Page refresh operation
- Browser tosses the current JavaScript environment when navigating to a different page
  - Problematic for JavaScript frameworks: URL (and cookies) are the only information preserved

## Problem with some web apps

- Initial: pages served from web server
  - Each page had a URL and app switched between pages served by web server
- Early JavaScript apps: Website a single page/URL with the JavaScript

Problem: Restart web app on navigation (Can lose a lot of work!)

```
window.onbeforeunload = function(e) { return 'All will be lost!'; }
```

- Users expect app in browser to do the right thing:
  - Navigate with forward and back buttons, browser page history
  - Navigate away and come back to the app
  - Bookmark a place in the app
  - Copy the URL from the location bar and share it with someone
  - Push the page refresh button on the browser

## Changing URL without page refresh

- Can change hash fragment in URL without reload

`http://example.com`

`http://example.com#fragment`

`http://example.com?id=3535`

`http://example.com?id=3535#fragment`

- HTML5 give JavaScript control of page reload

- Browser History API - `window.history` - Change URL without reloading page

# Deep linking

- Concept: the URL should capture the web app's context so that directing the browser to the URL will result the app's execution to that context
  - Bookmarks
  - Sharing
- Context is defined by the user interface designer!
  - Consider: Viewing information of entity and have an edit dialog open
  - Should the link point to the entity view or to the entity & dialog?
  - Does it matter if I'm bookmarking for self or sharing with others?
  - How about navigating away and back or browser refresh?

# Deep linking in Single Page Apps

Two approaches:

1. Maintain the app's context state in the URL
  - + Works for browser navigation and refresh
  - + User can copy URL from location bar
2. Provide a share button to generate deep linking URL
  - + Allows user to explicitly fetch a URL based on need
  - + Can keep URL in location bar pretty

Either way web app needs to be able to initialize self from deep linked URL

## Ugly URLs

`http://www.example.org/dirmod?sid=789AB8&type=gen&mod=Core+Pages&gid=A6CD4967199`

versus

`http://www.example.org/show/A6CD4967199`

What is that ugly thing in the location bar above my beautiful web application?

`https://www.flickr.com/photos/jarnasen/24593000826/in/explore-2016-01-26/`

## ReactJS support for SPA

- ReactJS has no opinion! Need 3rd party module.
- Example: React Router Version 5 <https://v5.reactrouter.com/>
  - Idea: Use URL to control conditional rendering
  - Newer version 6 is available using same concepts as v5 but slightly different syntax
- Various ways of encoding information in URL
  - In fragment part of the URL: [HashRouter](#)
  - Use HTML5 URL handler: [BrowserRouter](#)
- Import as a module:

```
import {HashRouter, Route, Link, Redirect} from 'react-router-dom';
```

# Example React Router V5

```
<HashRouter>
  <div>
    ...
    <Route path="/states" component={States} />
    ...
    <Link to="/states">States</Link>
    ...
  </div>
</HashRouter>
```

- JSX block controlled by URL enclosed in HashRouter
- Route will render the component if URL matches.
- Use Link component to generate hyperlink:  
`<a href="#/states">  
 States  
</a>`

# Passing parameters with React Router

- Parameter passing in URL

```
<Route  
  path="/Book/:book/ch/:chapter"  
  component={BookChapterComponent}  
/>
```

- Parameters put in prop.match of the component

```
function BookChapterComponent({ match }) {  
  return ( <div>  
    <h3>Book: {match.params.book}</h3>  
    <h3>Chapter: {match.params.chapter}</h3>  
  </div> );  
}
```

```
<Link to="/Book/Moby/ch/1">  
  Moby  
</Link>
```

**Book: Moby**  
**Chapter: 1**

## Route: component=, render=, children=

- component={BookChapterComponent}
  - Mounts components on match (unmounts on URL change)
  - Passes match object with: params, url, history
- render={props => <BookChapterComponent book={props.match.params.book} chapter={props.match.params.chapter} />}
  - Calls function with props having match object from above.
  - Doesn't mount/unmount component (does update it)
- children= - Like render= except is called regardless of the match
  - match will be null if URL doesn't match
  - Useful if you want to have something always render but only active on matching URL.

Multiple route matches have precedence order: component, render, children

Switch is useful with multiple Route - Renders the first matching one

# Example

ID	Name	Phone	Email	Birthdate	Last Access	Rating	Base	Salary	Score
24	Alexandra Nixon	(422) 644-3498	necituctu@osu.edu	12/01/1981	February 29, 2003	-1	41%	\$46,672	7.5
17	Allisa Monroe	(859) 974-4442	adina.lie@ucam.edu	02/14/1990	April 30, 2003	6	95%	\$103,999	5.9
10	Baker Osborn	(378) 371-0559	turman.bella@ac.edu	03/26/1970	July 23, 2005	-7	61%	\$2,868	0.1
9	Caldwell Larson	(850) 562-3177	mlt@dekor.com	07/20/1983	June 22, 2004	-3	81%	\$63,736	7.5
25	Chanissa Manning	(438) 395-9392	nb.vuatu@nacon.org	07/01/1980	April 02, 2005	-8	11%	\$32,193	3.5
46	Charity Hahn	(395) 200-9188	ac@Quicquid.edu	08/04/1976	January 17, 2009	-2	80%	\$3,246	3.5
30	Doran Hodge	(304) 536-8850	seigne@lanceet.org	08/15/1978	February 21, 2007	6	6%	\$26,057	0.1
1	Ezekiel Hart	(627) 536-4760	toron@est.ca	12/02/1962	March 26, 2009	-7	2%	\$73,229	6.9
12	Fletcher Briggs	(992) 962-9419	amet.arted@enhouse.edu	08/12/1971	December 12, 2006	7	23%	\$142,448	8.9
40	Fritz Benton	(323) 353-2984	al@lumunus.com	10/02/1957	June 16, 2002	-5	2%	\$75,654	8.9
								\$3,442,036	
						0.8	44.1%	\$70,246	5.19

- What to keep in URL: table length, viewport in table, search box, sort column, etc.
- Is it different for bookmark or share? Nav away and back?

## Example: Not everything goes in URL

Angular JS Crud Grid  
This is a running demo of the AngularJS crud grid application at [softwarejuancarlos.com](http://softwarejuancarlos.com).

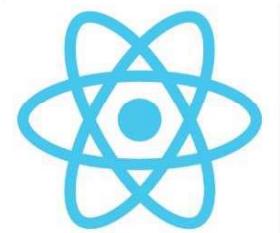

Angular JS CRUD Grid  
[softwarejuancarlos.com](http://softwarejuancarlos.com)

	Name	Expire Date	
<input type="checkbox"/>	Milk	Sunday, October 5, 2014	
<input type="checkbox"/>	Eggs	Sunday, October 5, 2014	
<input type="checkbox"/>	Steak	2x 400g	Saturday, September 20, 2014
<input type="checkbox"/>	Oranges

React JS

# React JS Intro

# What Is React ?

## What is React ?

- React JS is a open source JavaScript libraries engineered to make it as simple and efficient as possible to build client-side web and hybrid mobile applications based on JavaScript, HTML5, and CSS.

- JavaScript framework for writing the web applications
  - Like AngularJS - Snappy response from running in browser
  - Less opinionated: only specifies rendering view and handling user interactions
- Uses Model-View-Controller pattern
  - View constructed from Components using pattern
  - Optional, but commonly used HTML templating
- Minimal server-side support dictated
- Focus on supporting for programming in the large and single page applications
  - Modules, reusable components, testing, etc.

# Prerequisites

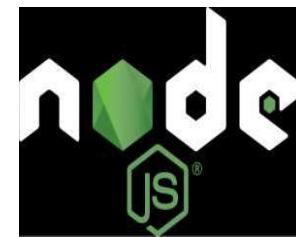

- HTML, CSS and JS
- Basics of Type Script

**HTML**

**CSS**

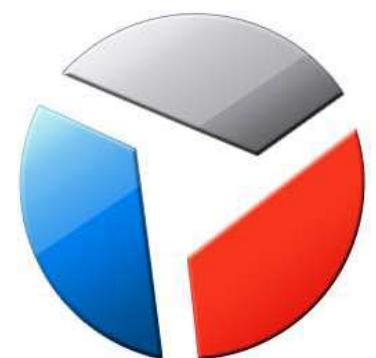

## React is designed to meet the following application needs:

- Add interactivity to an existing page.
- Create a new end-to-end client-side web application using JavaScript, HTML5, CSS, and best practices for responsive design.
- Create a hybrid mobile application that looks and feels like a native iOS, Android or Windows application.
- It is a “ Structural Framework for Dynamic Web Apps ”.
- Helps build interactive, modern Web Applications by increasing abstraction between the Developer and Common Web App Development Tasks.

# Why React ?

## Why React ?

- Modular Approach
- Re Usable Code
- Development Quicker and easier
- Unit Testable
- Many JS Providers

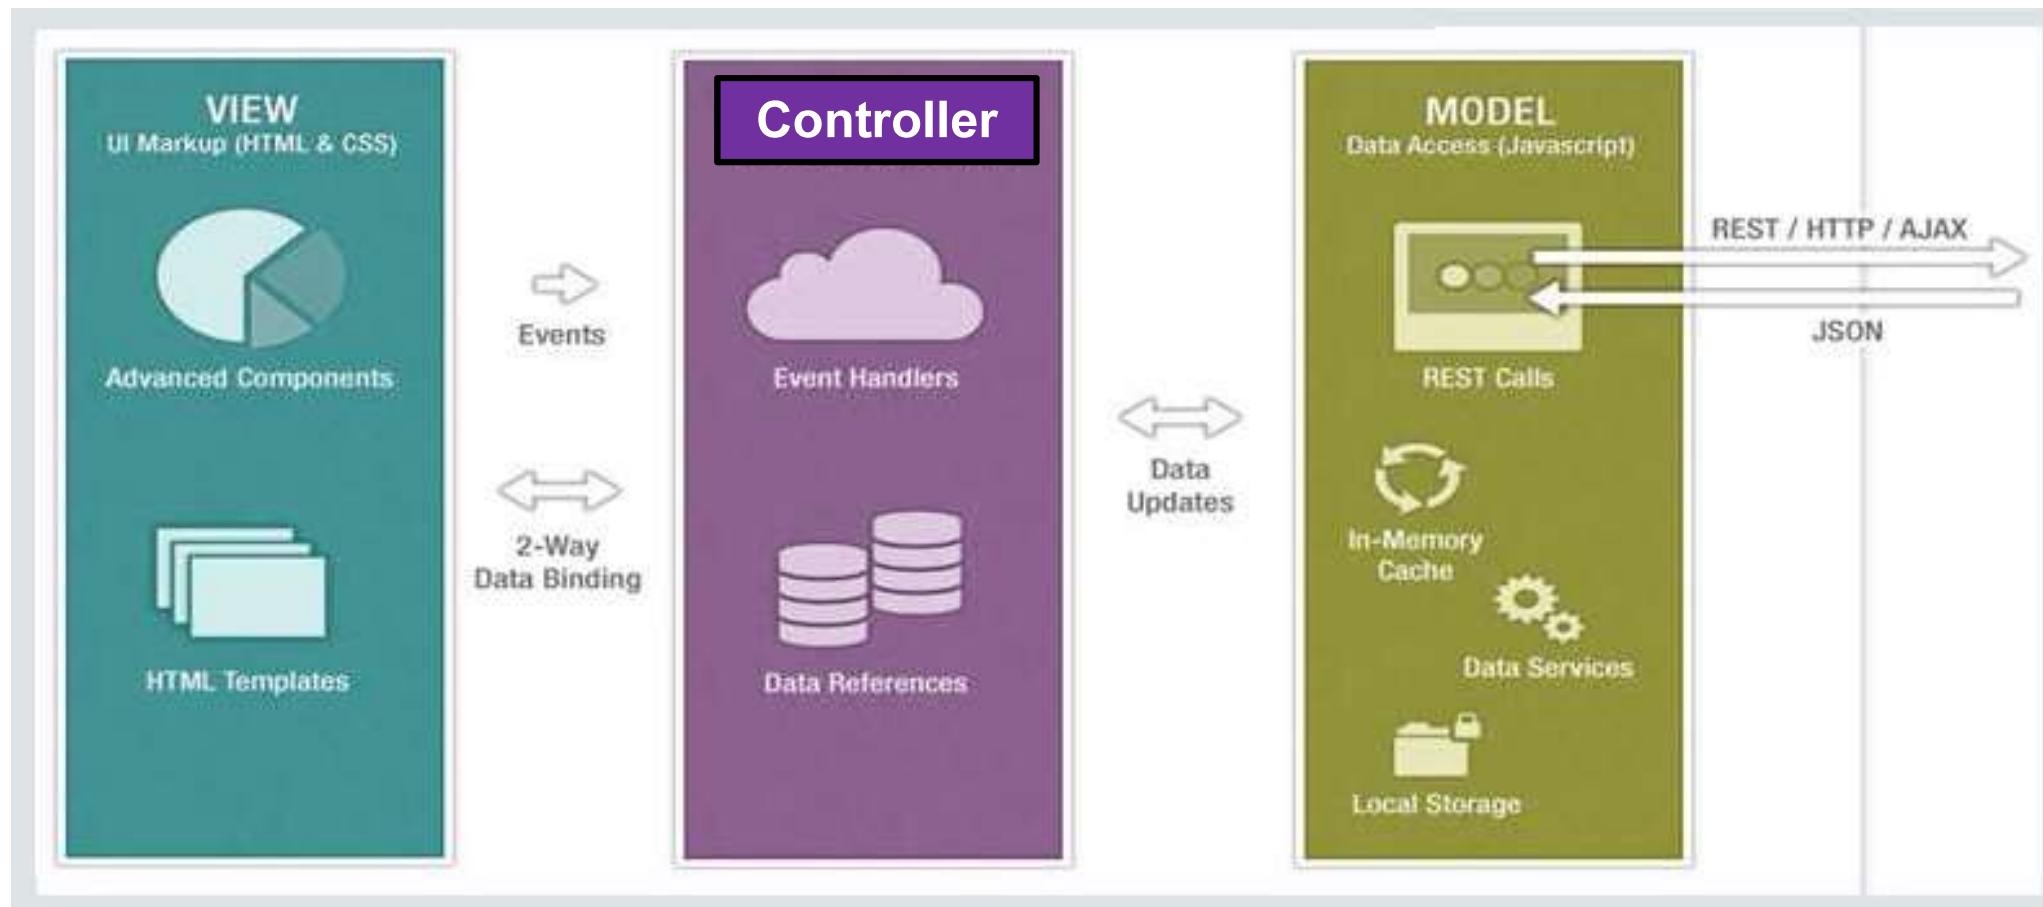

Cont ...

- Declarative programming should be used for building UI and associating Software Components.
- “Imperative Programming is Very good for Business Logic”
- React encourages loose coupling between Presentation, Data and Logic Components.

# React Architecture

- React supports the Model-View-Controller (MVC) architectural design pattern.

# The MVC

# Why React is becoming Famous ?

## 1. One Way Binding

- Binding Data to the UI Components.
- Data Binding is Automatic Synchronization Between VIEW ( HTML ) and MODEL ( Simple JS Variables ).
- MVC( Model View Controller)

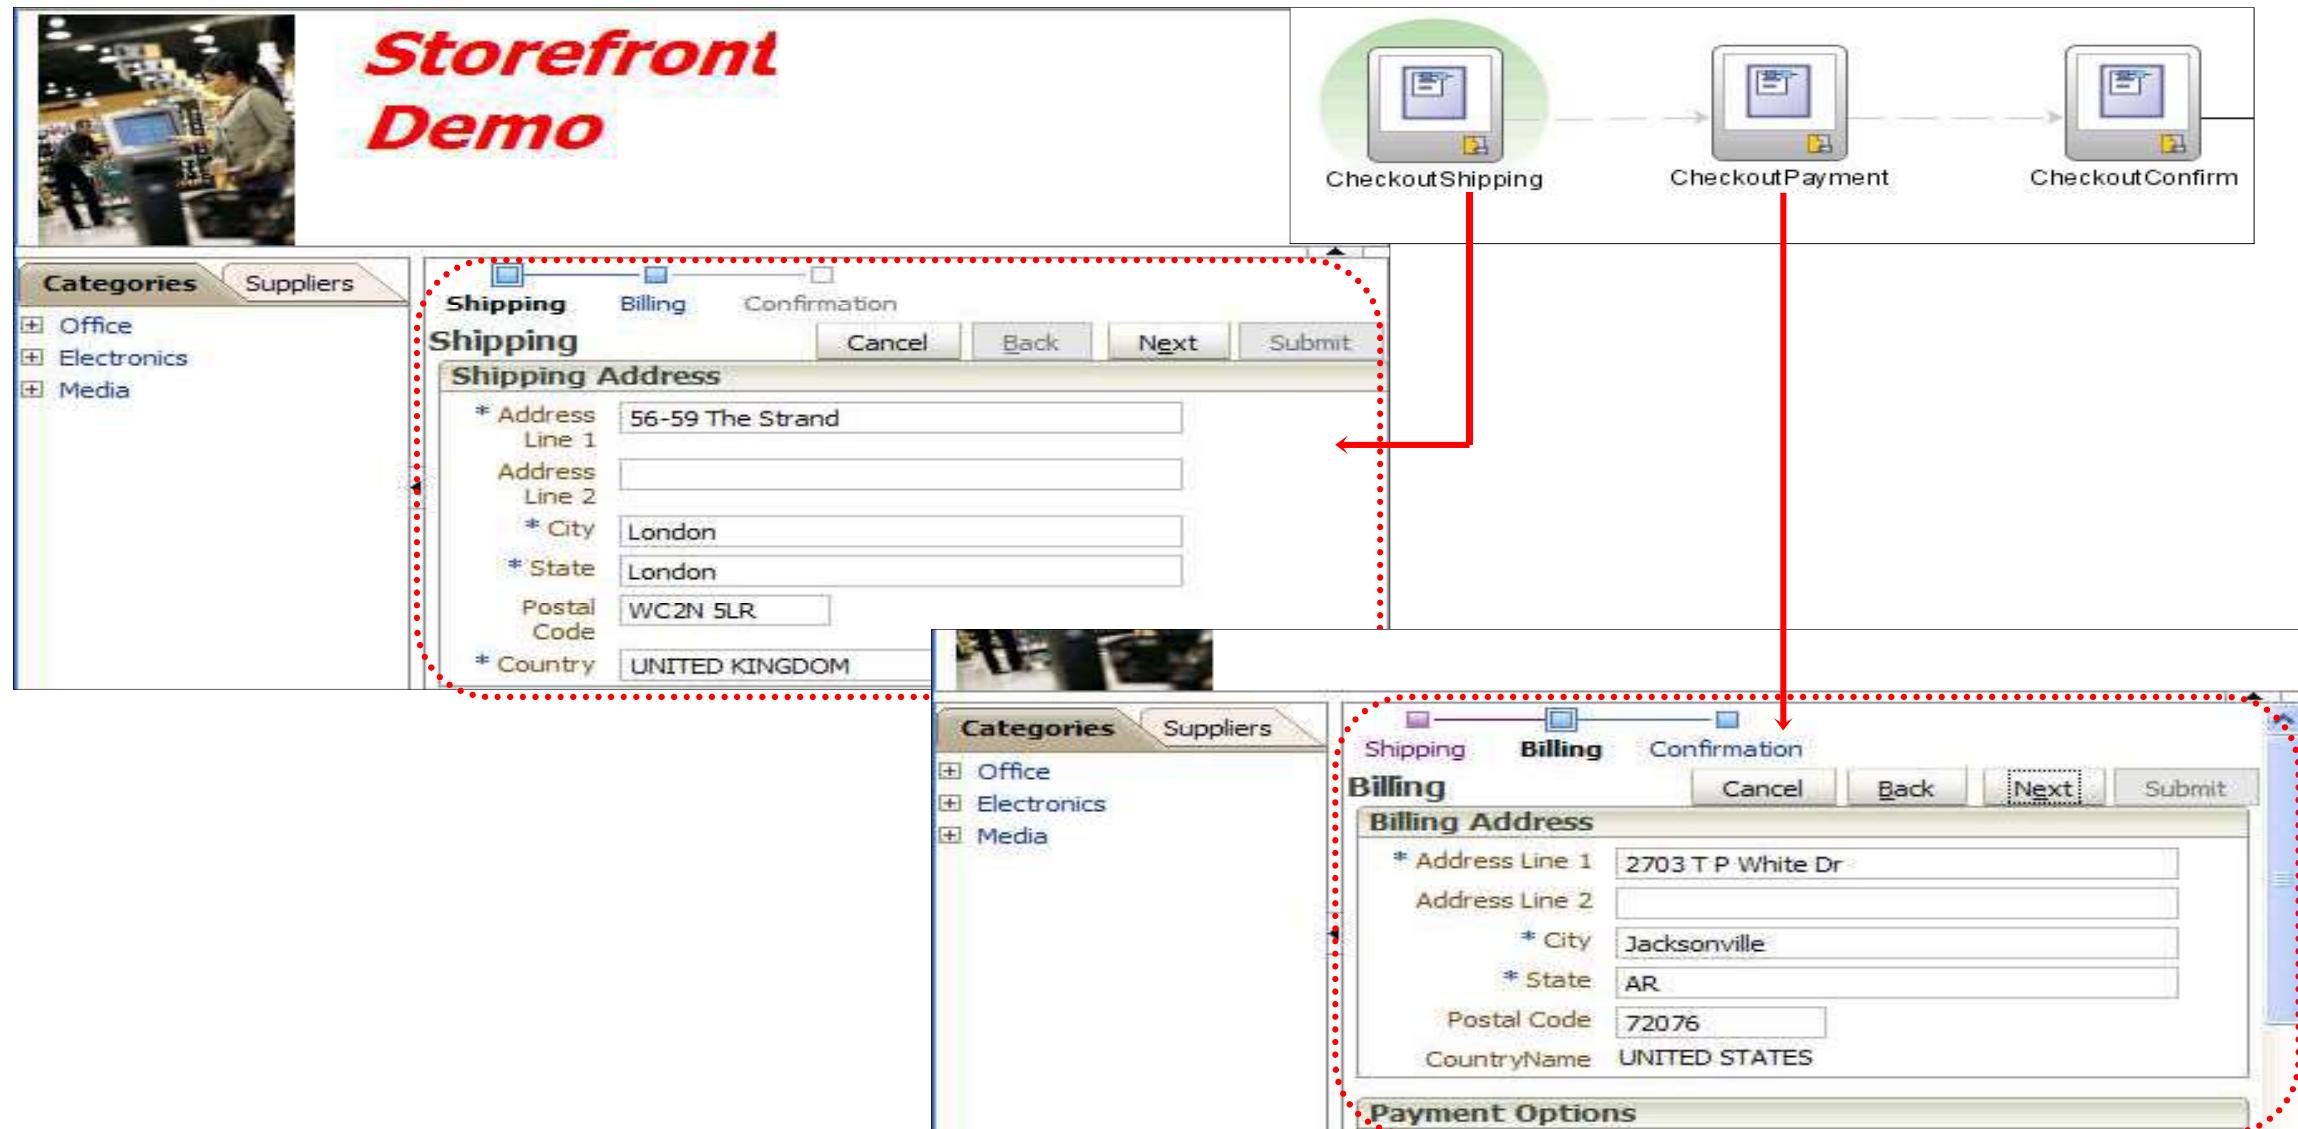

## 2. Structure front End Code

- A Pure Separation of Concern
- HTML will be Focusing on UI ( VIEW )
- JavaScript Will Be Focusing on Model

### 3. Routing Support

- Navigation Support
- Focus is On SINGLE PAGE APPLICATION
- Whole Application Will be Revolved Around A Single Page , But Navigation will Take Place not Between Pages but in turn Between Fragments.
- Giving a Desktop Application Look and Feel.

# Using a Bounded Task Flow

4. Validation framework that provides UI element and component validation and data converters
5. Powered By React and There is a JS Community
6. Focus is on Developing Web Application Using Design Pattern
7. Messaging and event services for both Model and View layers
8. Caching services at the Model layer for performance optimization of pagination and virtual scrolling
9. Connection to data sources through Web services, such as Representational State Transfer (REST) or WebSocket
10. Support for Testing ( Eg : KARMA )
11. Logging and Security Support

## Hybrid Mobile Application Development Toolkit Features

- React includes support for hybrid mobile applications that run on iOS, Android, and Windows mobile devices within the Apache Cordova container.
- Apache Cordova enables you to use web technologies such as HTML5, CSS, and JavaScript to develop applications that you can deploy to mobile devices.
- Using the Cordova JavaScript APIs to access native device services, major mobile platforms such as Android, iOS, and Windows can be supported from a common code base.

# Hybrid Mobile Application Development

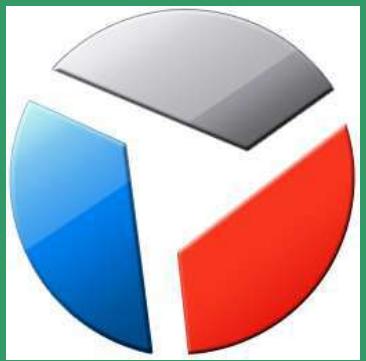

1. JavaScript and HTML in the same file (JSX)
2. Embrace functional programming
3. Components everywhere

# ReactJS Web Application Page

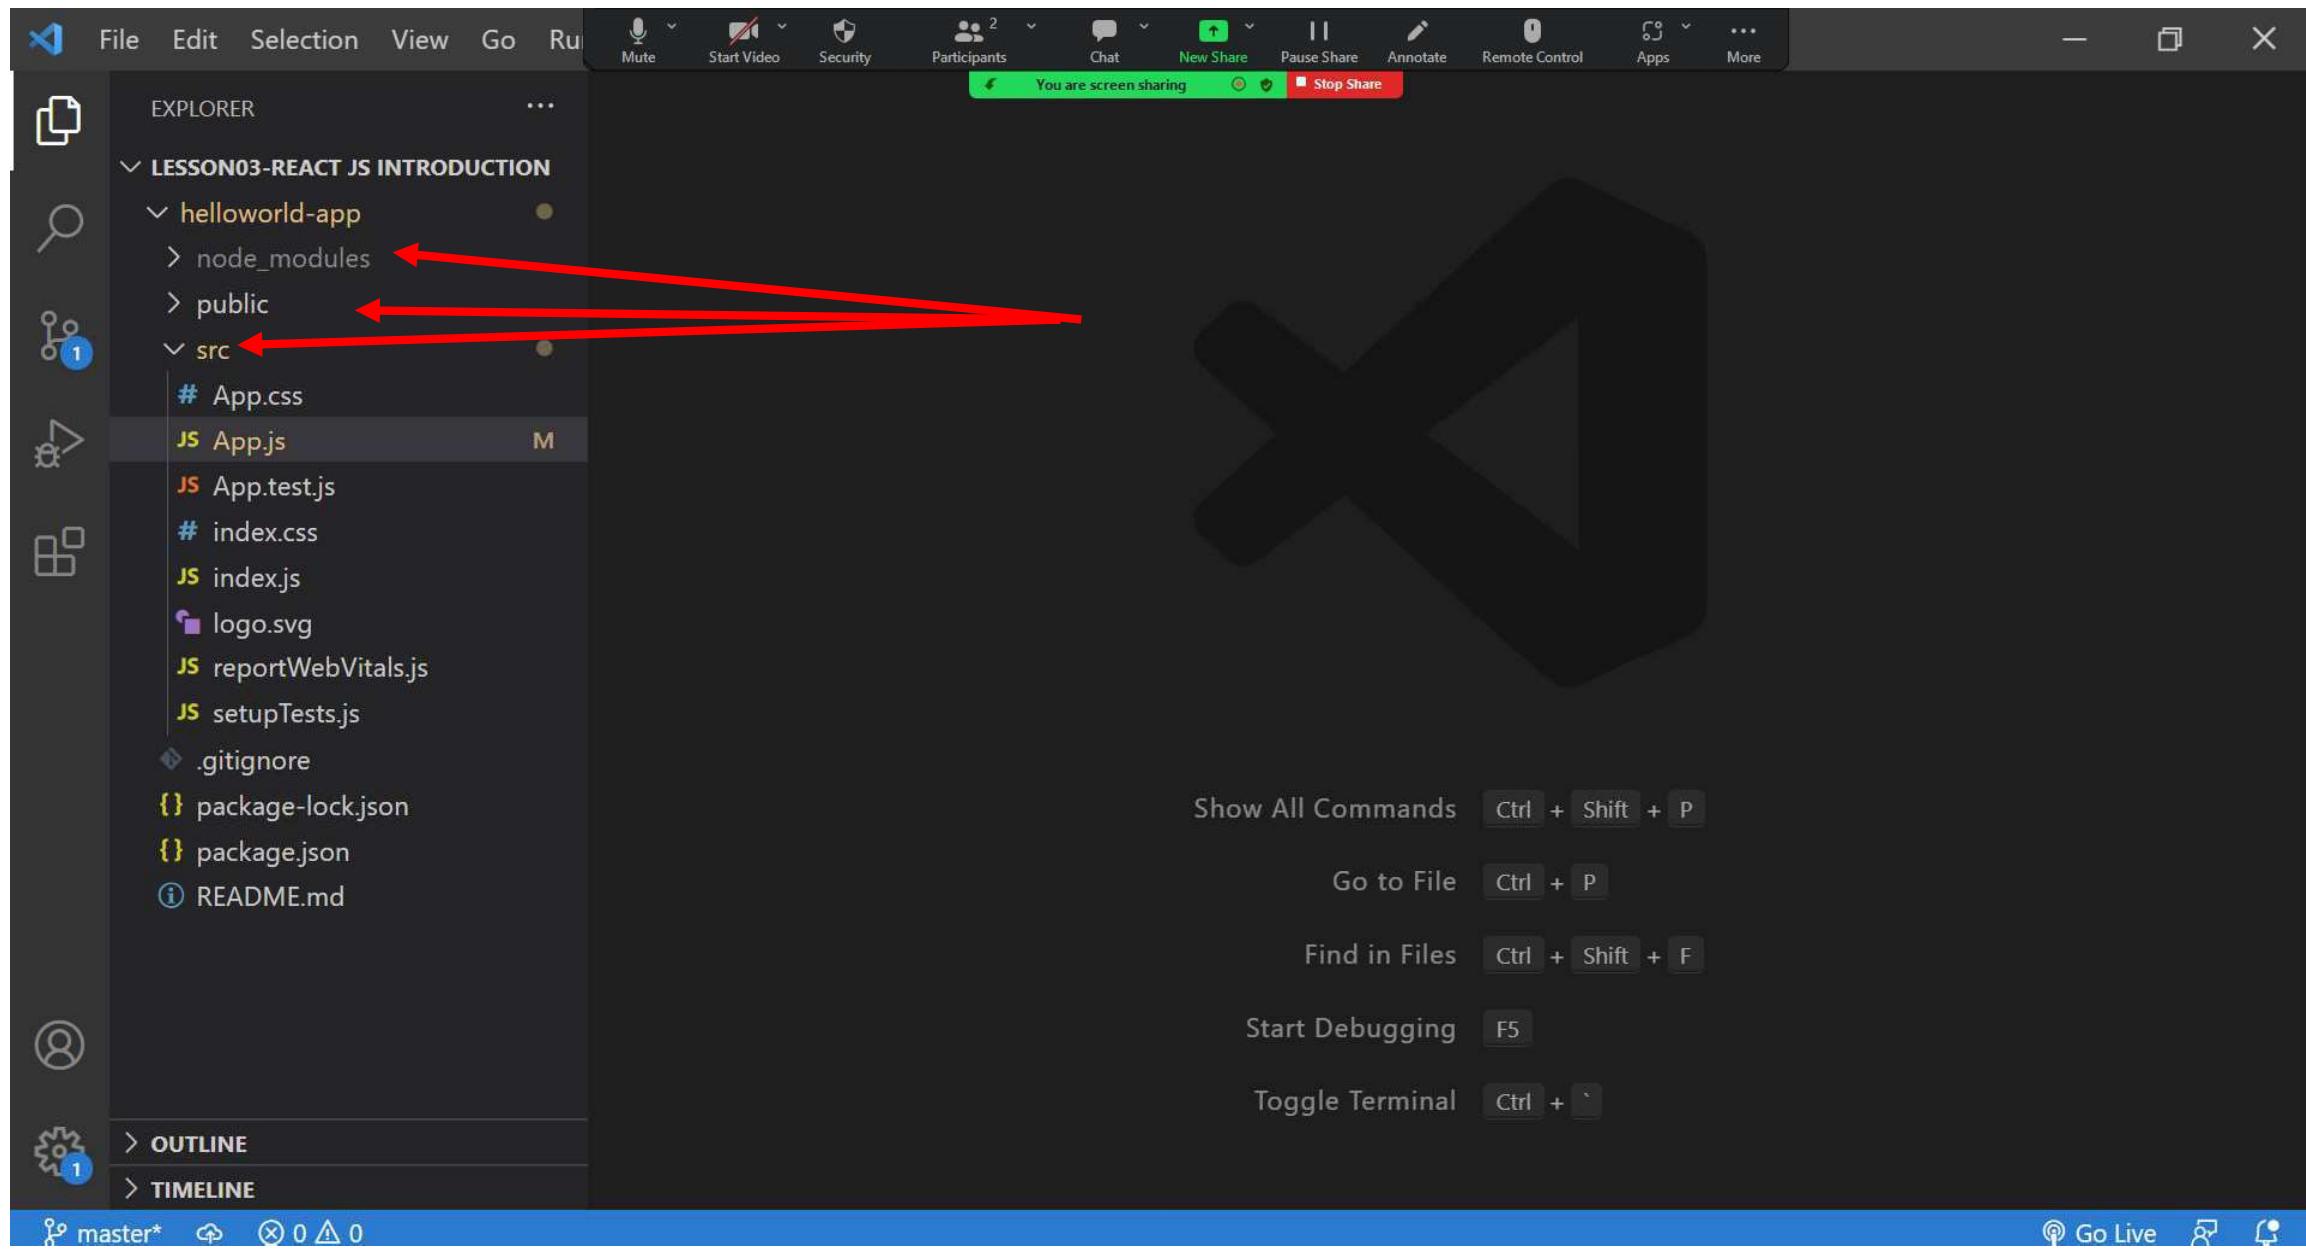

```
<!doctype html>
<html>
  <head>
    <title>CS142 Example</title>
  </head>
  <body>
    <div id="reactapp"></div> ←
    <script src=".webpackOutput/reactApp.bundle.js"></script>
  </body>
</html>
```

ReactJS applications come as a **JavaScript blob** that will use the DOM interface to write the view into the div.

# Package.json

The screenshot shows the Visual Studio Code interface with the following details:

- File Bar:** File, Edit, Selection, View, Go, Run, Terminal, Help.
- Title Bar:** package.json - Lesson03-React JS Introduction - Visual Studio Code.
- Explorer:** Shows the project structure under LESSON03-REACT JS INTRODUCTION, including helloworld-app, build, node\_modules, public, src, .gitignore, package-lock.json, package.json, and README.md.
- Editor:** The package.json file is open, displaying its contents. The code includes a "name" field, a "version" field, a "private" field set to true, a "dependencies" object listing various testing and React-related packages, a "scripts" object defining four command-line scripts ("start", "build", "test", "eject"), and an "eslintConfig" object with an "extends" field.
- Bottom Bar:** PROBLEMS, DEBUG CONSOLE, OUTPUT, TERMINAL.
- Status Bar:** You may serve it with a static server: master\*, Remaining Meeting Time: 03:52, Stop Share, Ln 14, Col 15, Spaces: 2, UTF-8, LF, JSON, Go Live, 2:38 PM, 3/1/2024.
- Taskbar:** Type here to search, iQGateway, browser icons (Edge, Chrome, Firefox), system icons (File Explorer, Task View, Taskbar icons).

# [ Src – A Place Where Developer Writes the Code Functionality ]

# Root Component [ App Component ]

The screenshot shows the Visual Studio Code interface with the following details:

- File Explorer:** Shows the project structure under "LESSON03-REACT JS INTRODUCTION". The "src" folder contains files: # App.css, JS App.js, JS App.test.js, # index.css, JS index.js, logo.svg, JS reportWebVitals.js, JS setupTests.js, .gitignore, package-lock.json, package.json, and README.md. The "App.js" file is currently selected.
- Code Editor:** The "App.js" file is open, displaying the following code:

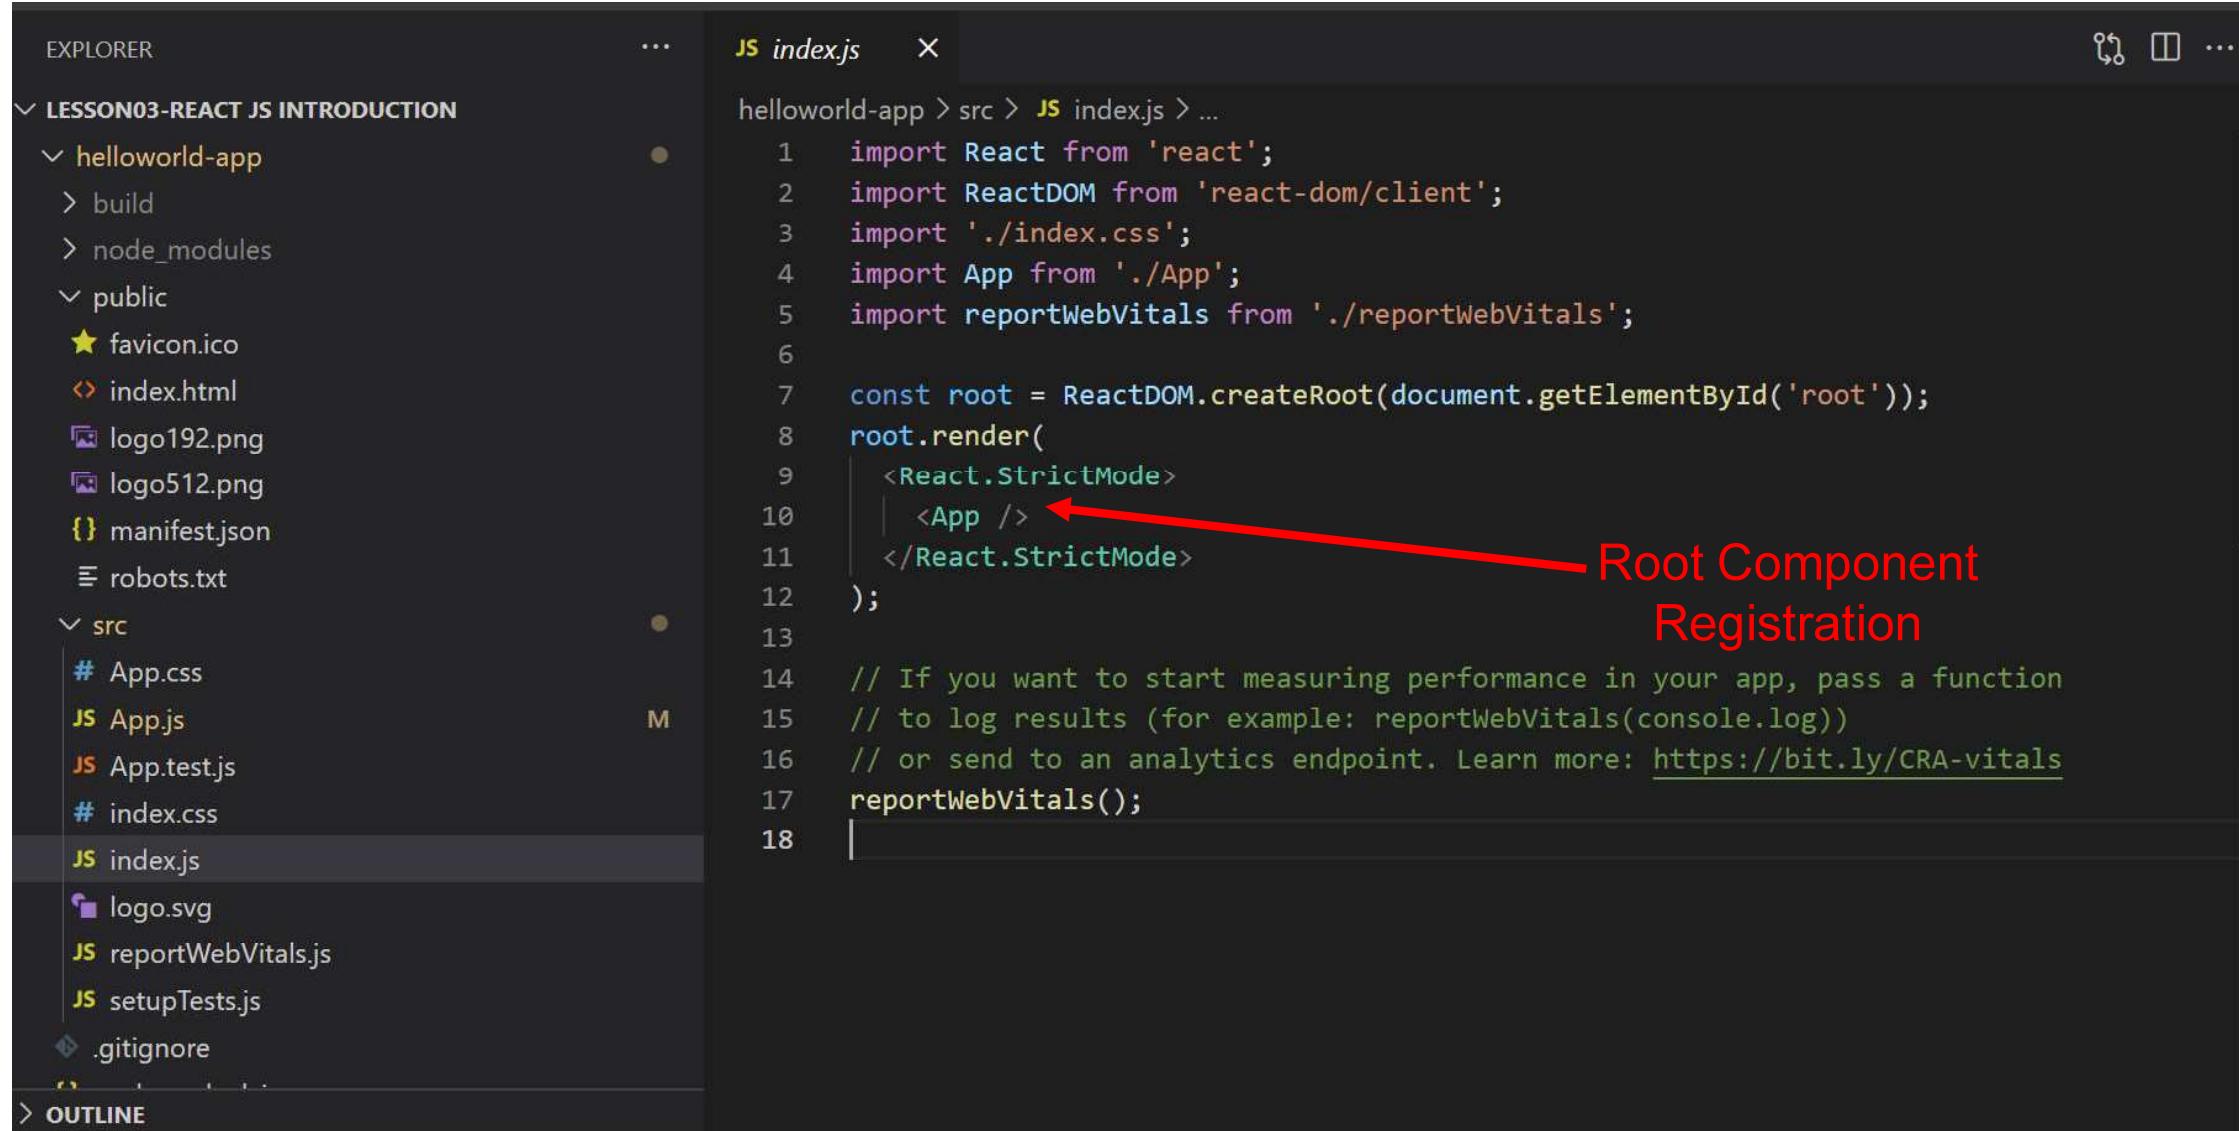

```
helloworld-app > src > JS App.js > App
1 import logo from './logo.svg';
2 import './App.css';
3
4 function App() {
5   return (
6     <div className="App">
7       <header className="App-header">
8         <img src={logo} className="App-logo" alt="logo" />
9         <p>
10          | Welcome to the World of React
11        </p>
12        <a
13          |   className="App-link"
14          |   href="https://reactjs.org"
15          |   target="_blank"
16          |   rel="noopener noreferrer"
17          |
18          |   Learn React
19        </a>
20      </header>
21    </div>
22  );
23}
24
25 export default App;
```

Annotations in red highlight specific parts of the code:

- A red arrow points from the text "Style Part of the Component" to the line `import './App.css';` in the code editor.
- A red arrow points from the text "View Part and Model Part of the Component" to the opening `

` tag of the component.

# Registering the Root Component

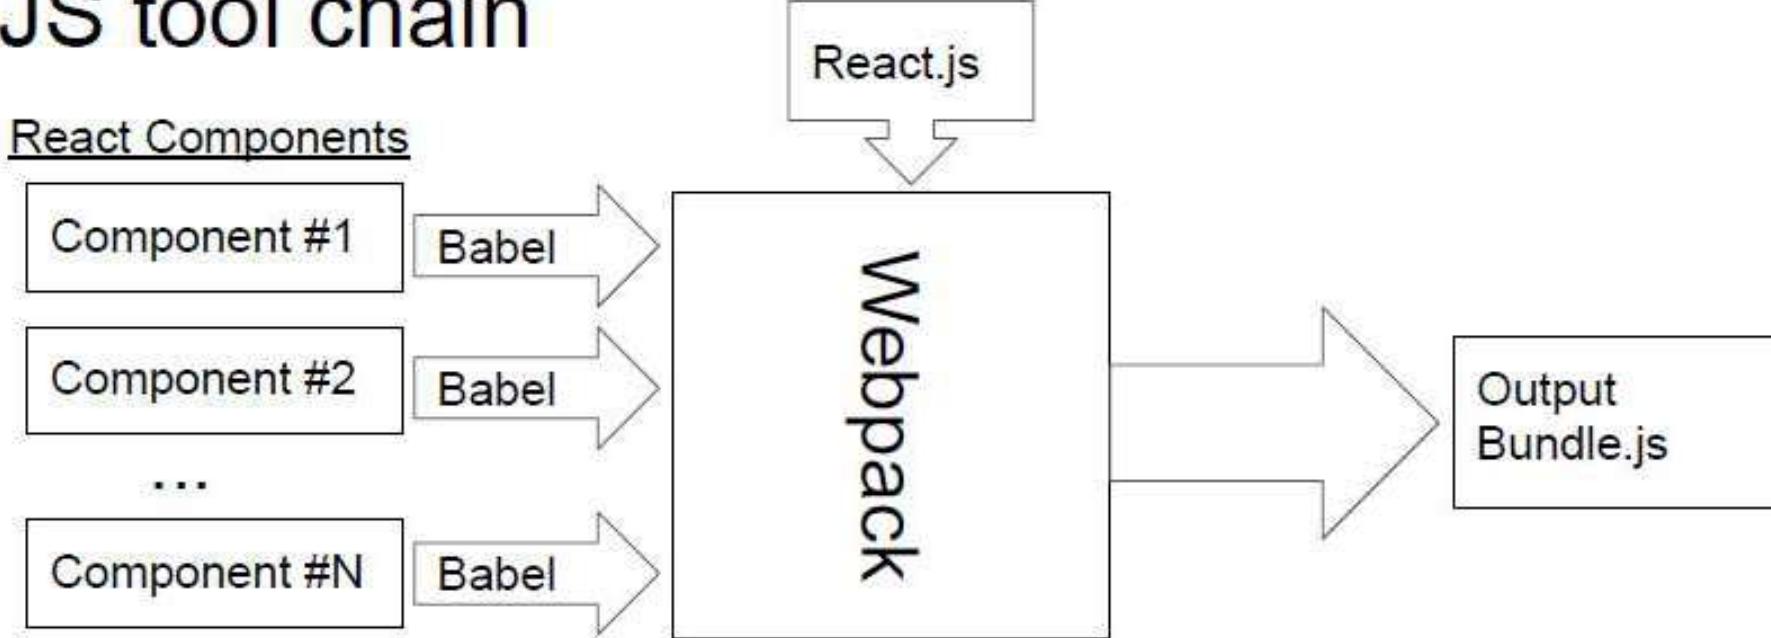

The screenshot shows a VS Code interface with the following details:

- EXPLORER** sidebar: Shows the project structure under **LESSON03-REACT JS INTRODUCTION**, including **helloworld-app** (with build, node\_modules, public), **src** (with App.css, App.js, App.test.js, index.css, index.js, logo.svg, reportWebVitals.js, setupTests.js), and .gitignore.
- index.js** file content:

```
helloworld-app > src > JS index.js > ...
1 import React from 'react';
2 import ReactDOM from 'react-dom/client';
3 import './index.css';
4 import App from './App';
5 import reportWebVitals from './reportWebVitals';
6
7 const root = ReactDOM.createRoot(document.getElementById('root'));
8 root.render(
9   <React.StrictMode>
10    <App />
11   </React.StrictMode>
12 );
13
14 // If you want to start measuring performance in your app, pass a function
15 // to log results (for example: reportWebVitals(console.log))
16 // or send to an analytics endpoint. Learn more: https://bit.ly/CRA-vitals
17 reportWebVitals();
18 |
```
- A red arrow points to the `<App />` line in the code, with the text "Root Component Registration" written in red to its right.

# ReactJS tool chain

## ReactJS tool chain

**Babel** - Transpile language features (e.g. ECMAScript, JSX) to basic JavaScript

**Webpack** - Bundle modules and resources (CSS, images)

Output loadable with single script tag in any browser

## JavaScript and HTML *in the same file*

HTML

CSS

JS

JSX

CSS or JSS

Traditional  
approach

React  
approach

## JSX: The React programming language

### JSX: the React programming language

```
const first = "Aaron";
const last  = "Smith";

const name = <span>{first} {last}</span>

const list = (
  <ul>
    <li>Dr. David Stotts</li>
    <li>{name}</li>
  </ul>
);

const listWithTitle = (
  <>
    <h1>COMP 523</h1>
    <ul>
      <li>Dr. David Stotts</li>
      <li>{name}</li>
    </ul>
  </>
);
```

“React is just JavaScript”

# Functional Programming

1. Functions are “first class citizens”
2. Variables are immutable
3. Functions have no side effects

# Functional Programming

## Functional programming

Functions are “**first class citizens**”

This means functions can be...

1. Saved as **variables**
2. Passed as **arguments**
3. **Returned** from functions

```
let add = function() {  
  console.log('Now adding numbers');  
  const five = 3 + 2;  
};
```

```
function performTask(task) {  
  task();  
  console.log('Task performed!');  
}  
  
performTask(add);
```

```
function foo() {  
  return function() {  
    console.log('What gets printed?');  
  };  
}  
  
foo  
foo();  
foo()();
```

# Functional programming

Variables are **immutable**

**Tip:** Use `const` instead of `let` to declare variables!

```
let a = 4;  
  
a = 2; // Mutates `a`
```

```
let b = [1, 2, 3];  
  
b.push(4); // Mutates `b`  
  
let c = [...b, 4]; // Does not mutate `b`
```

# Functional programming

Functions have **no side effects**

```
const b = [];

function hasSideEffects() {
  b = [0];
}
```

# Components

Components are **functions** for user interfaces

Functions help break  
your code into small,  
reusable pieces

Math function:

Component function:

# Anatomy of a React component

## Anatomy of a React **component**

```
export default function MyComponent(props) {  
  return <div>Hello, world! My name is {props.name}</div>;  
}  
  
const html = <MyComponent name="aaron" />;
```

The component is just a function

Inputs are passed through a single argument called "props"

The function outputs HTML

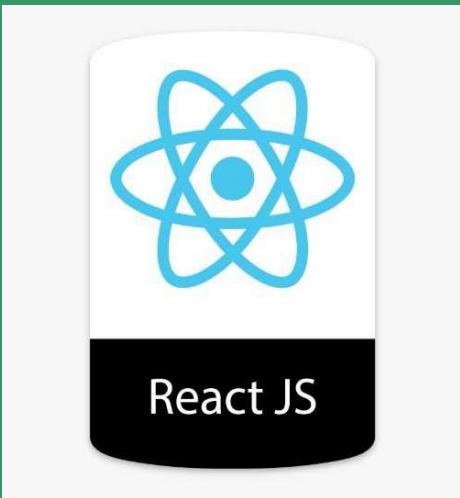

The function is **executed** as if it was an HTML tag

Parameters are passed in as HTML attributes

# Component **rendering**

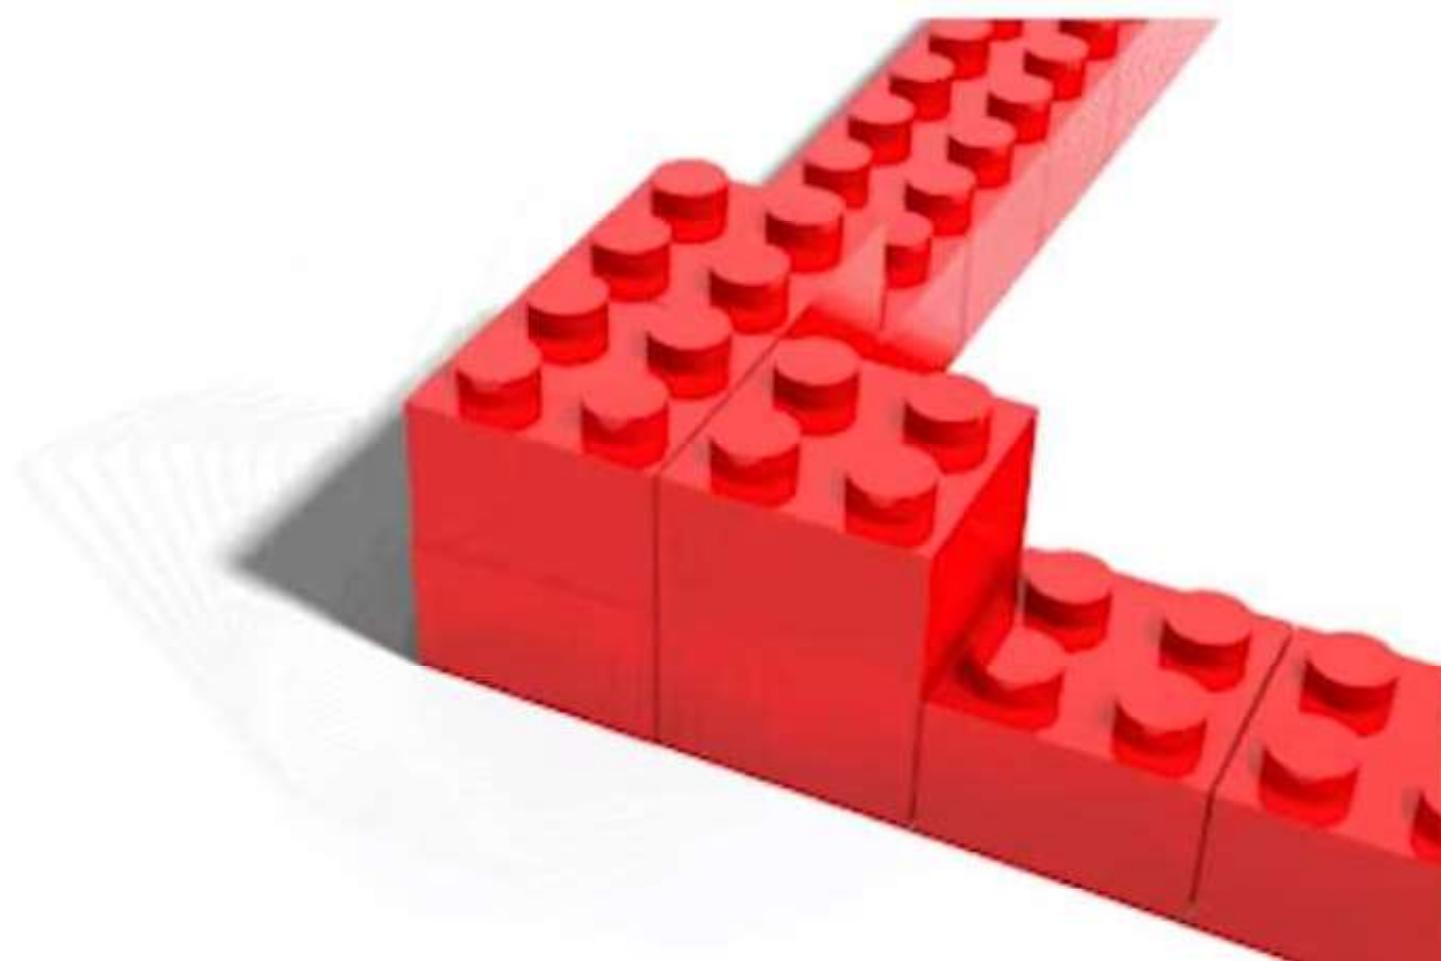

- When a component function **executes**, we say it “**renders**”
- Assume components may re-render at any time

Our job is to ensure that  
every time the component re-renders,  
the correct output is produced

# The Components

Angular Components are the Building Blocks Like

Cont ...

## Traditional Developments

- HTML which is the static portion of your application and then you write your JavaScript which is the dynamic portion of the application.
- The JavaScript is kind of embedded into your HTML so when the HTML loads the JavaScript also gets loaded

# Show Current Date and Time

## This is how We Do in Traditional Application

Add a div and paragraph

Code to get date/time  
Get the paragraph DOM element  
Update value

# How Do We Make it Dynamic

**HTML**

Add a div and paragraph

Add button

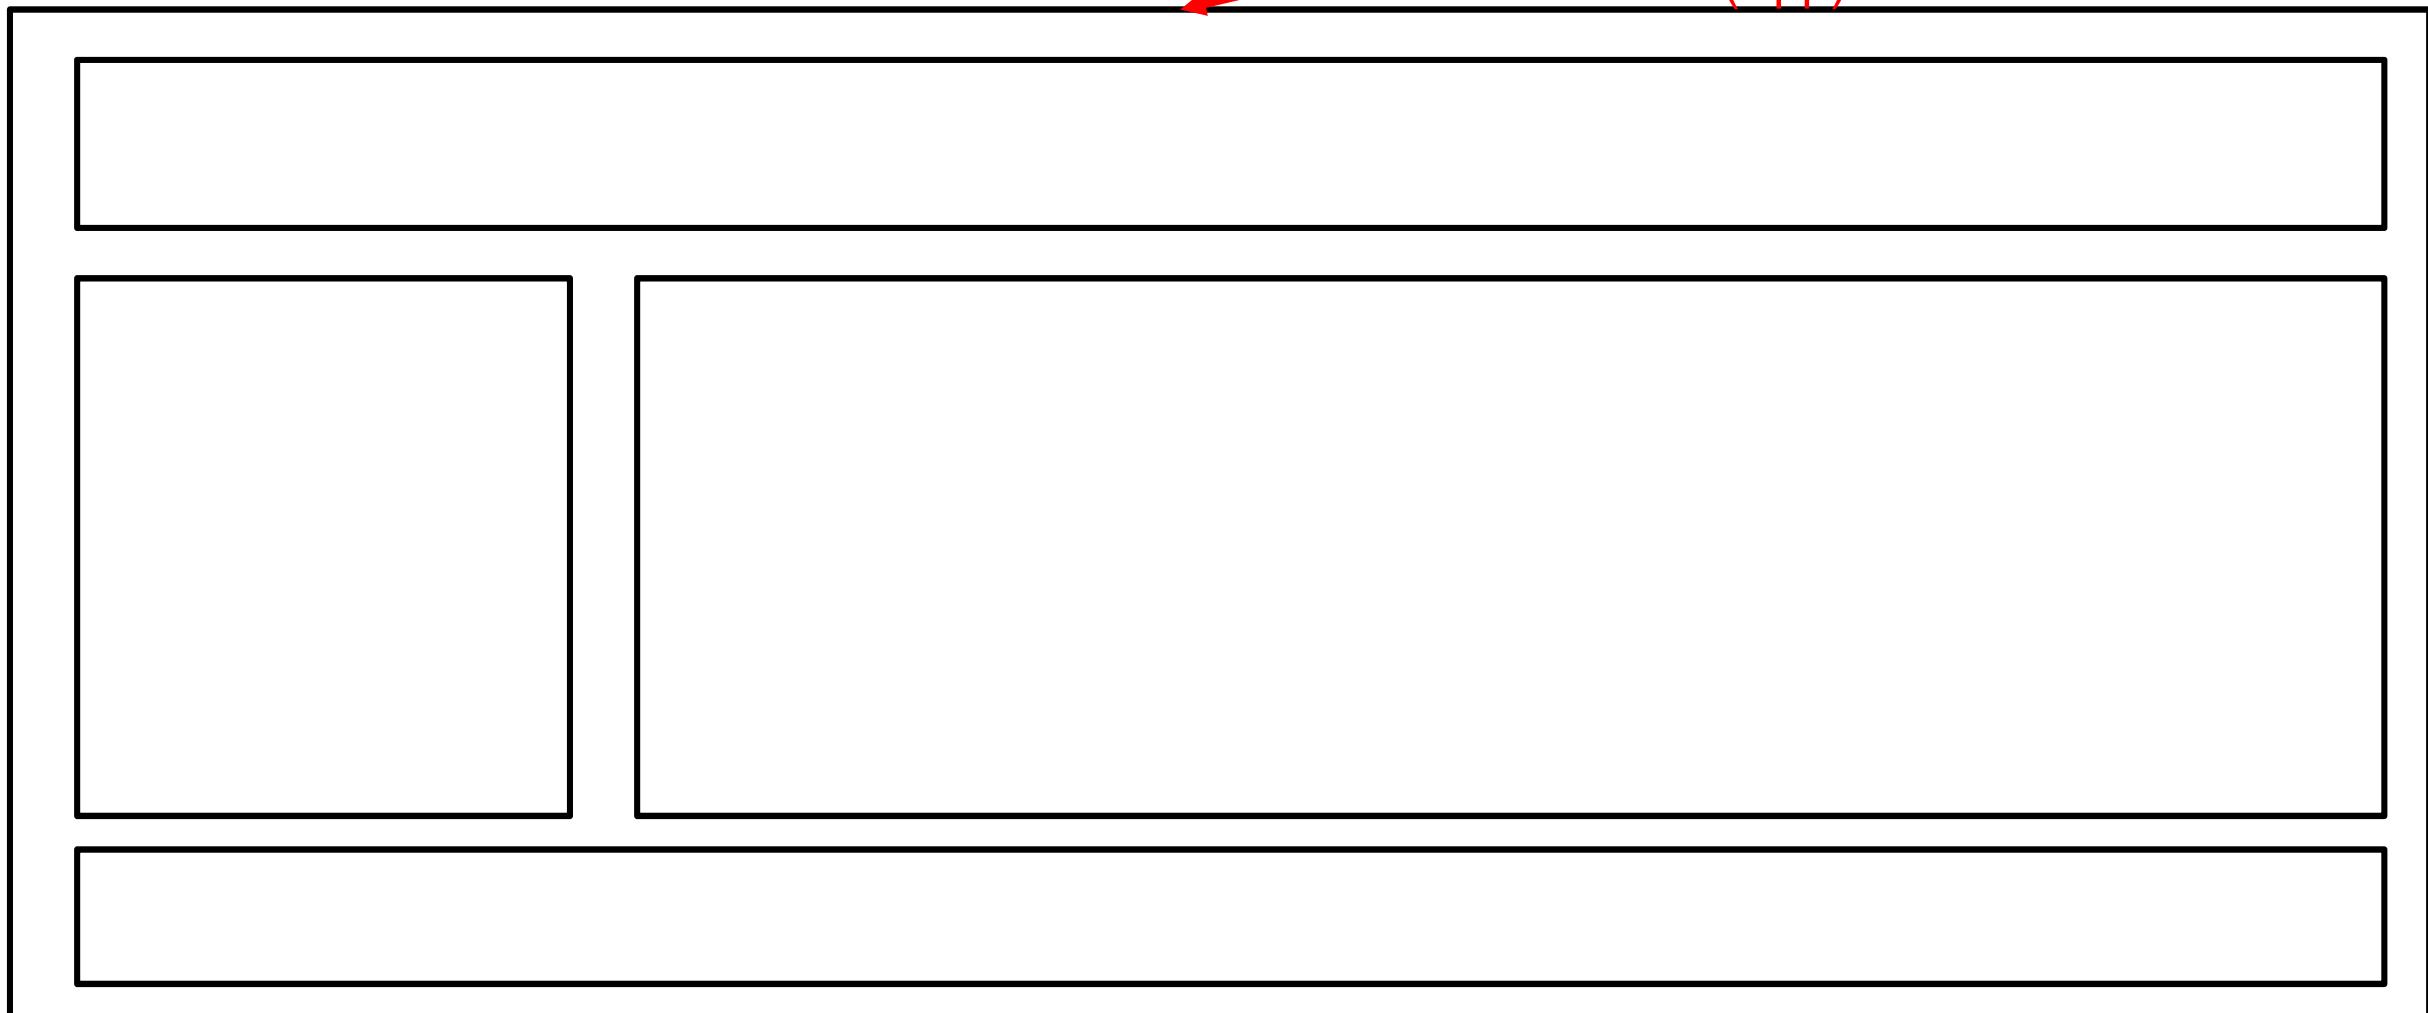

**JS**

Code to get date/time  
Get the paragraph DOM element  
Update value  
Code function to handle  
button click

# Component Based Approach

- In React applications we do not have this implicit divide at least in the mentioned module we don't have to think about it when we creating something
  - What is the HTML side
  - What is the JavaScript side
- In React We think about is components
- React has a component based approach to developing web applications

Root Component  
(App)

## header

- So every significant portion of real estate on our page which can be self-sufficient which knows what to do with that area can be split and created as a component
- This is the approach we use in developing an React Application.
- We are going to create this entity which contains HTML and JavaScript together in it right so this is a self-sufficient piece of web application that can be plugged in somewhere else and that knows what to do.

- Creating a component assign a name to that component write assign a selector that selector is what a consumer can use to call and render that component

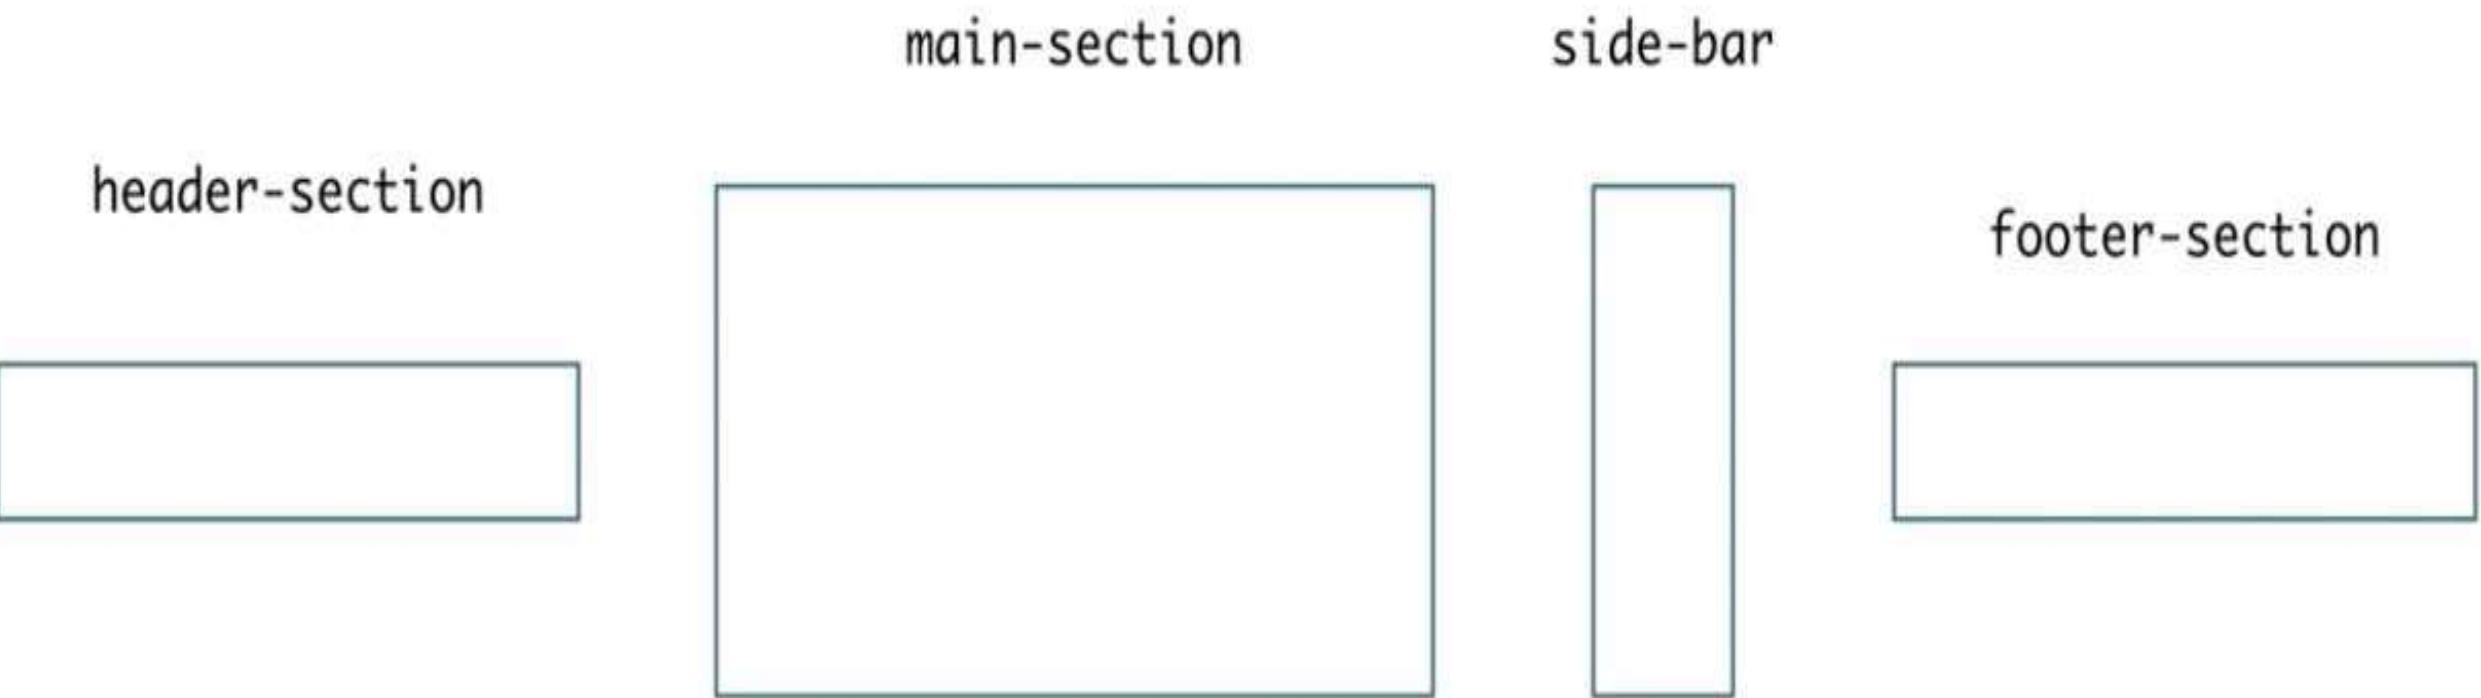

header

header-section

<header-section></header-section>

# Component Based Development

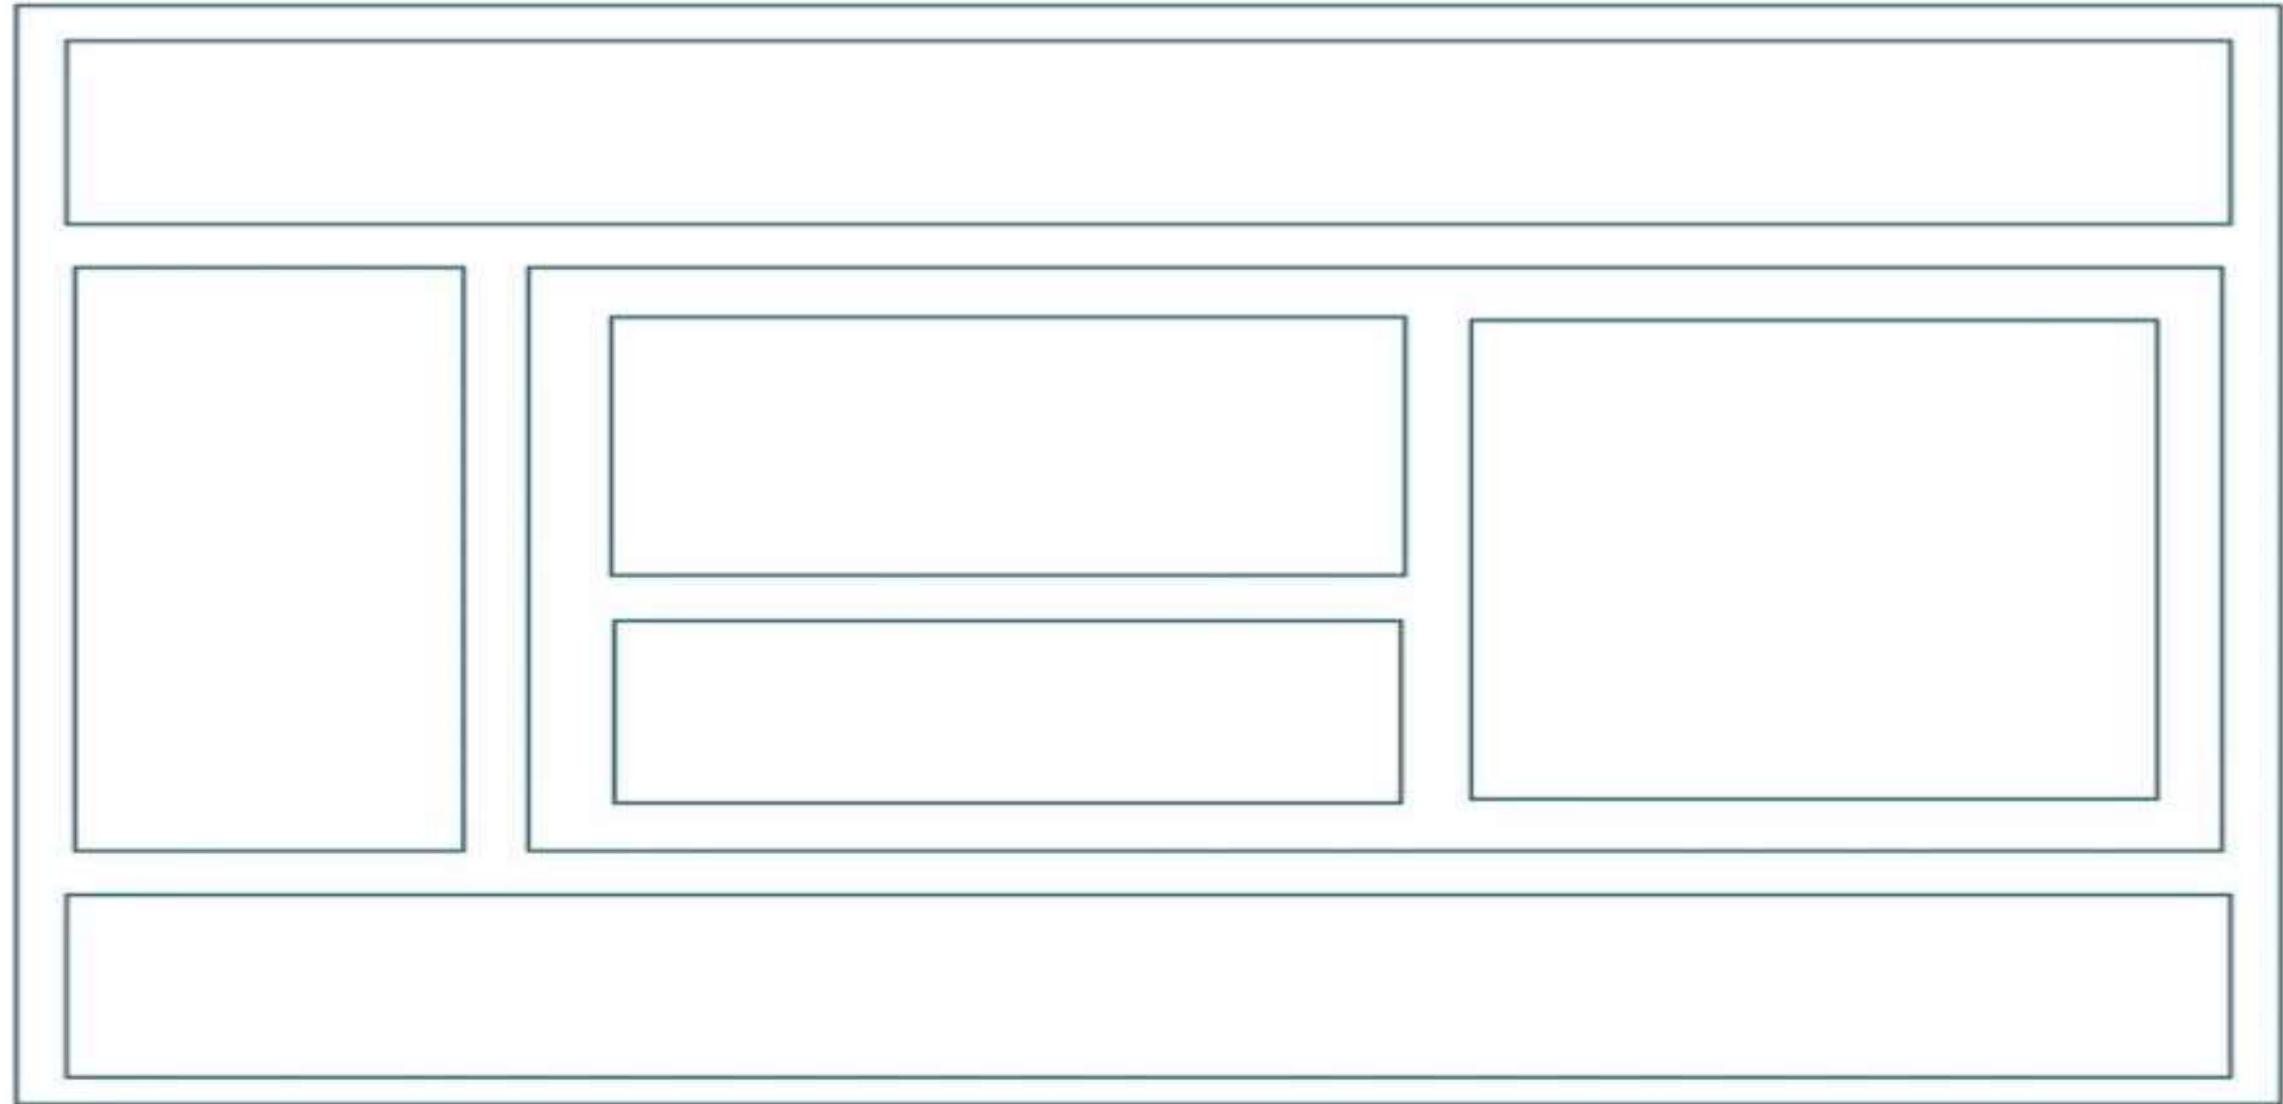

# Components on a Page

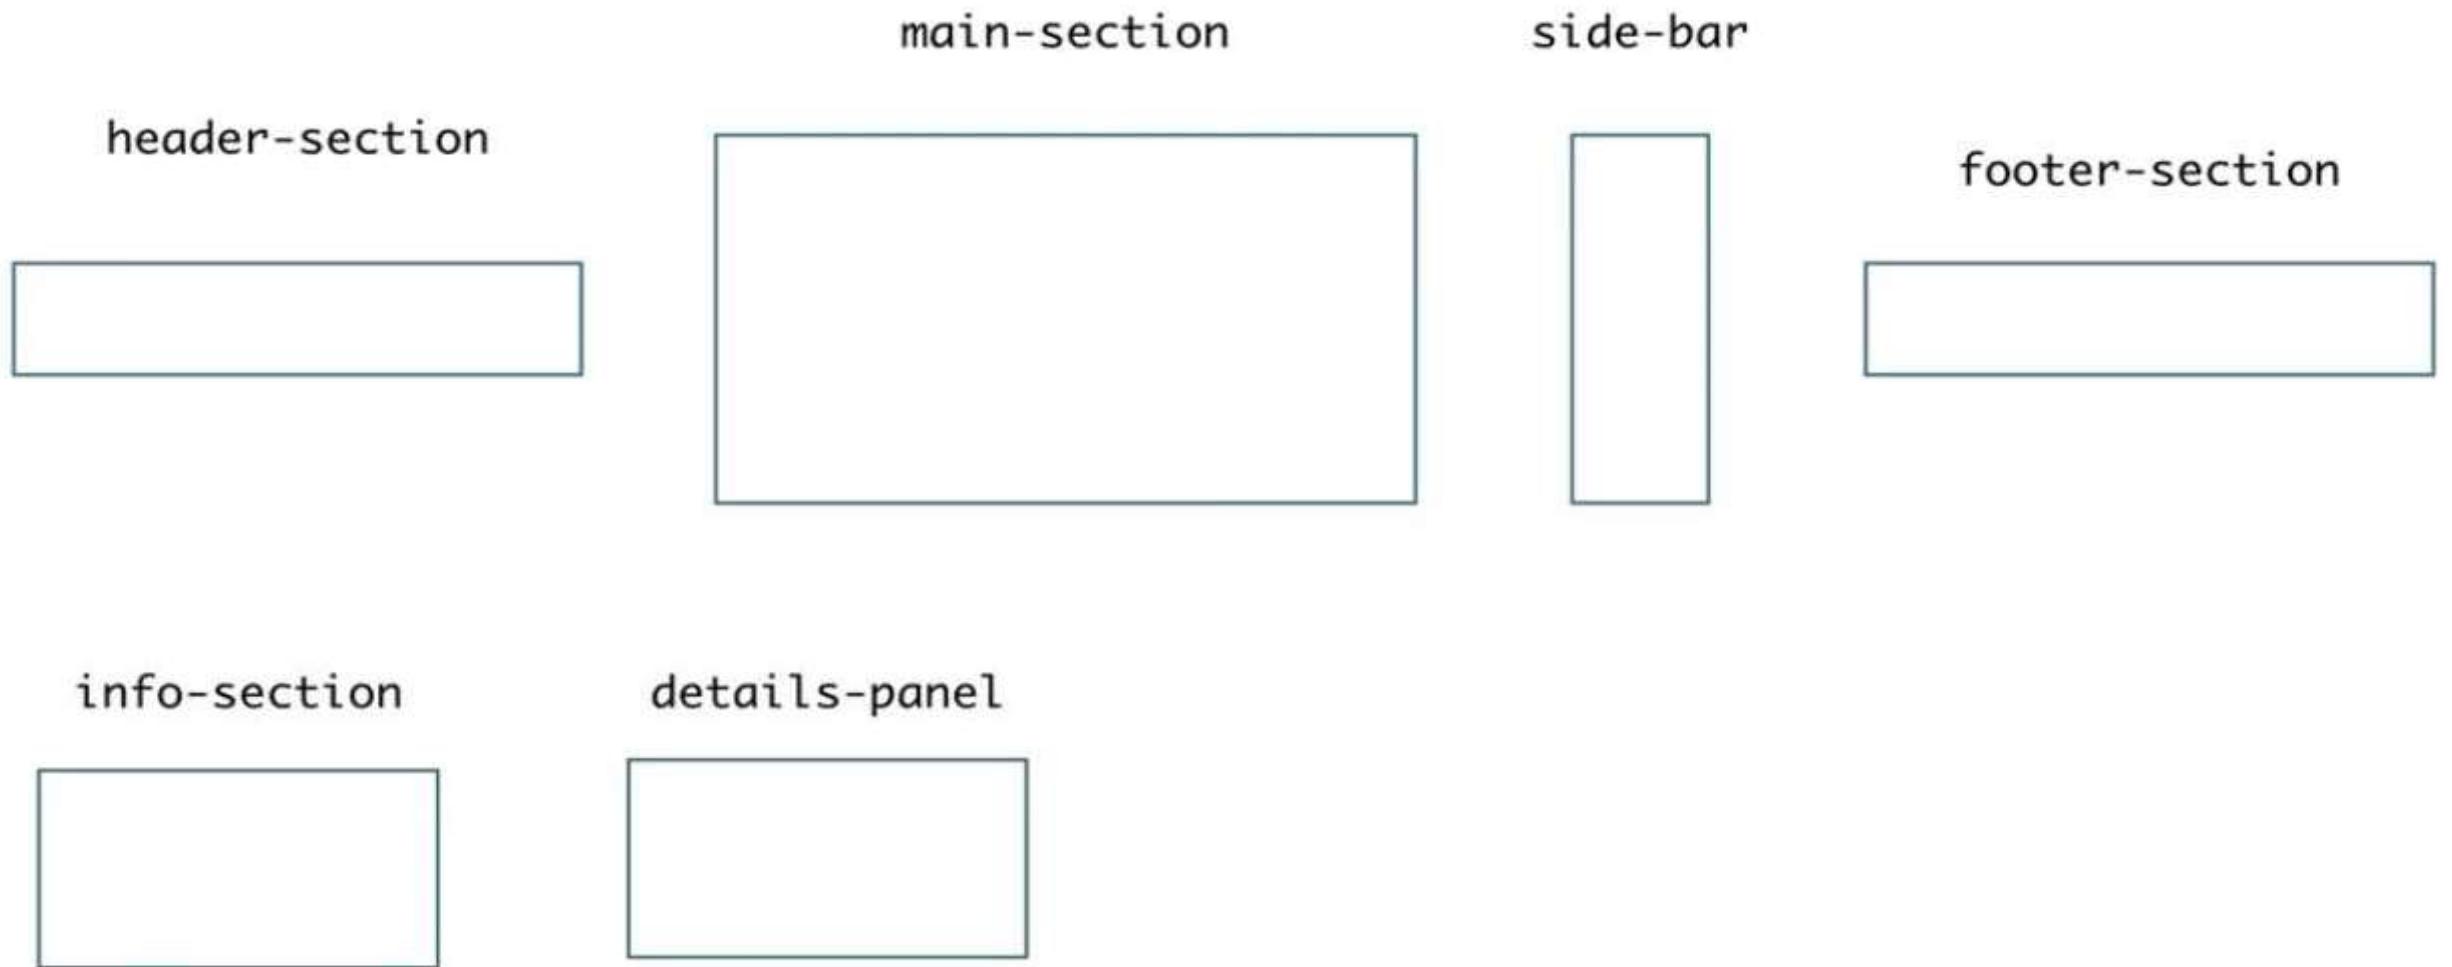

```
<header-section></header-section>

<main-section></main-section>

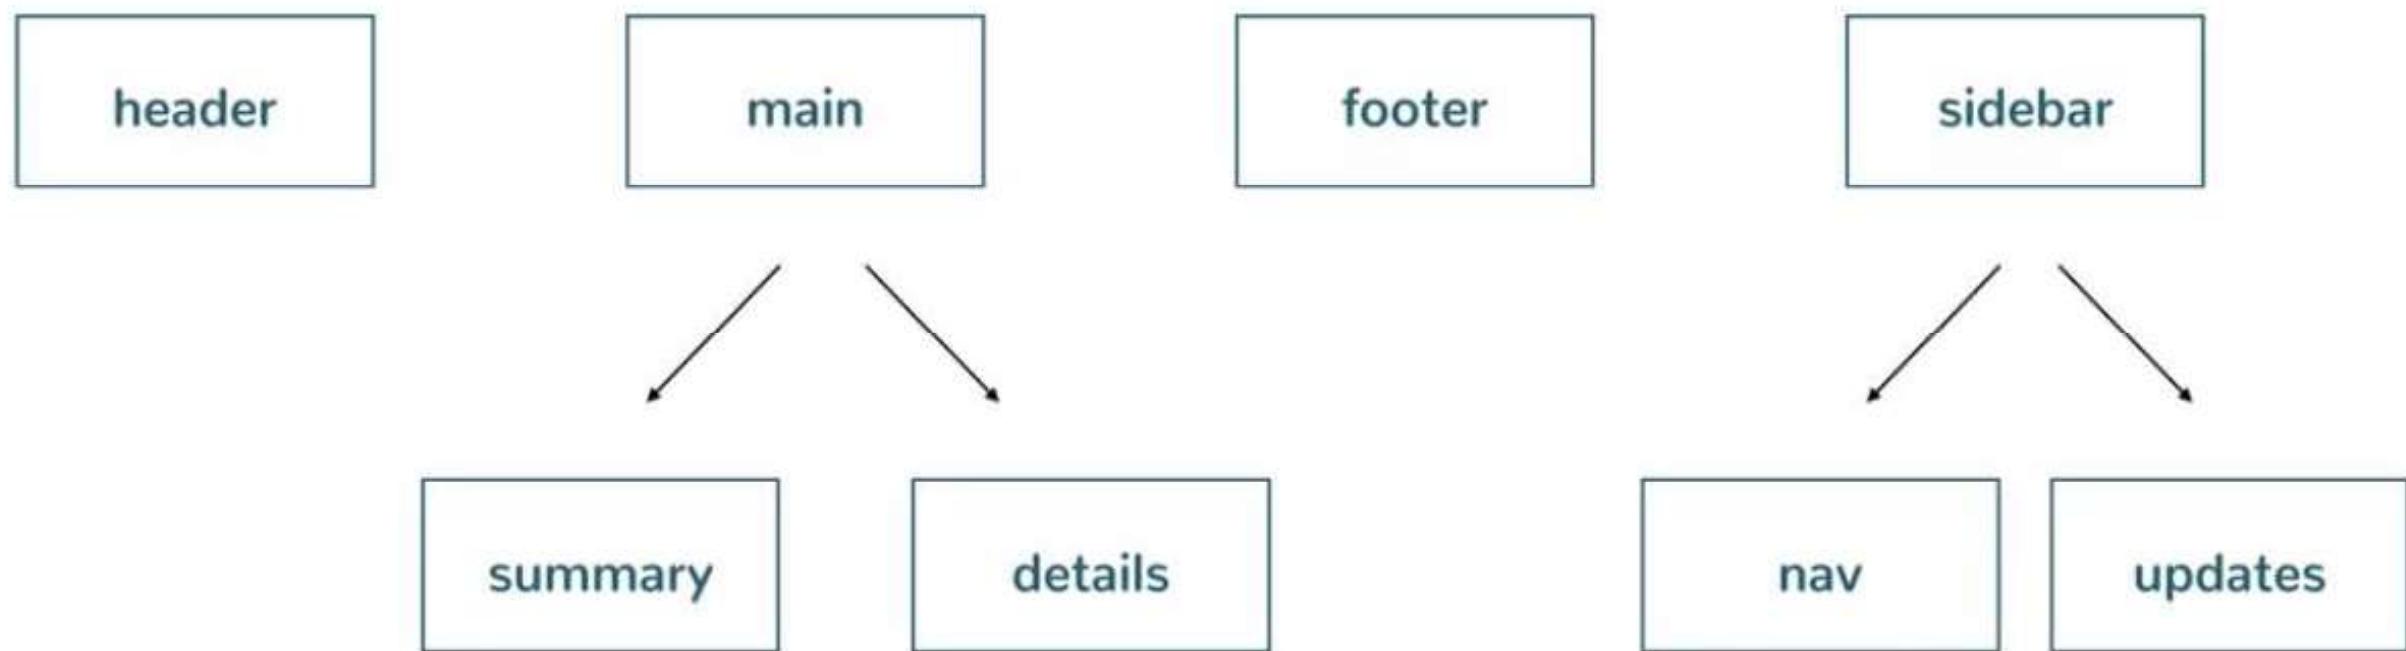

<side-bar></side-bar>

<footer-section></footer-section>
```

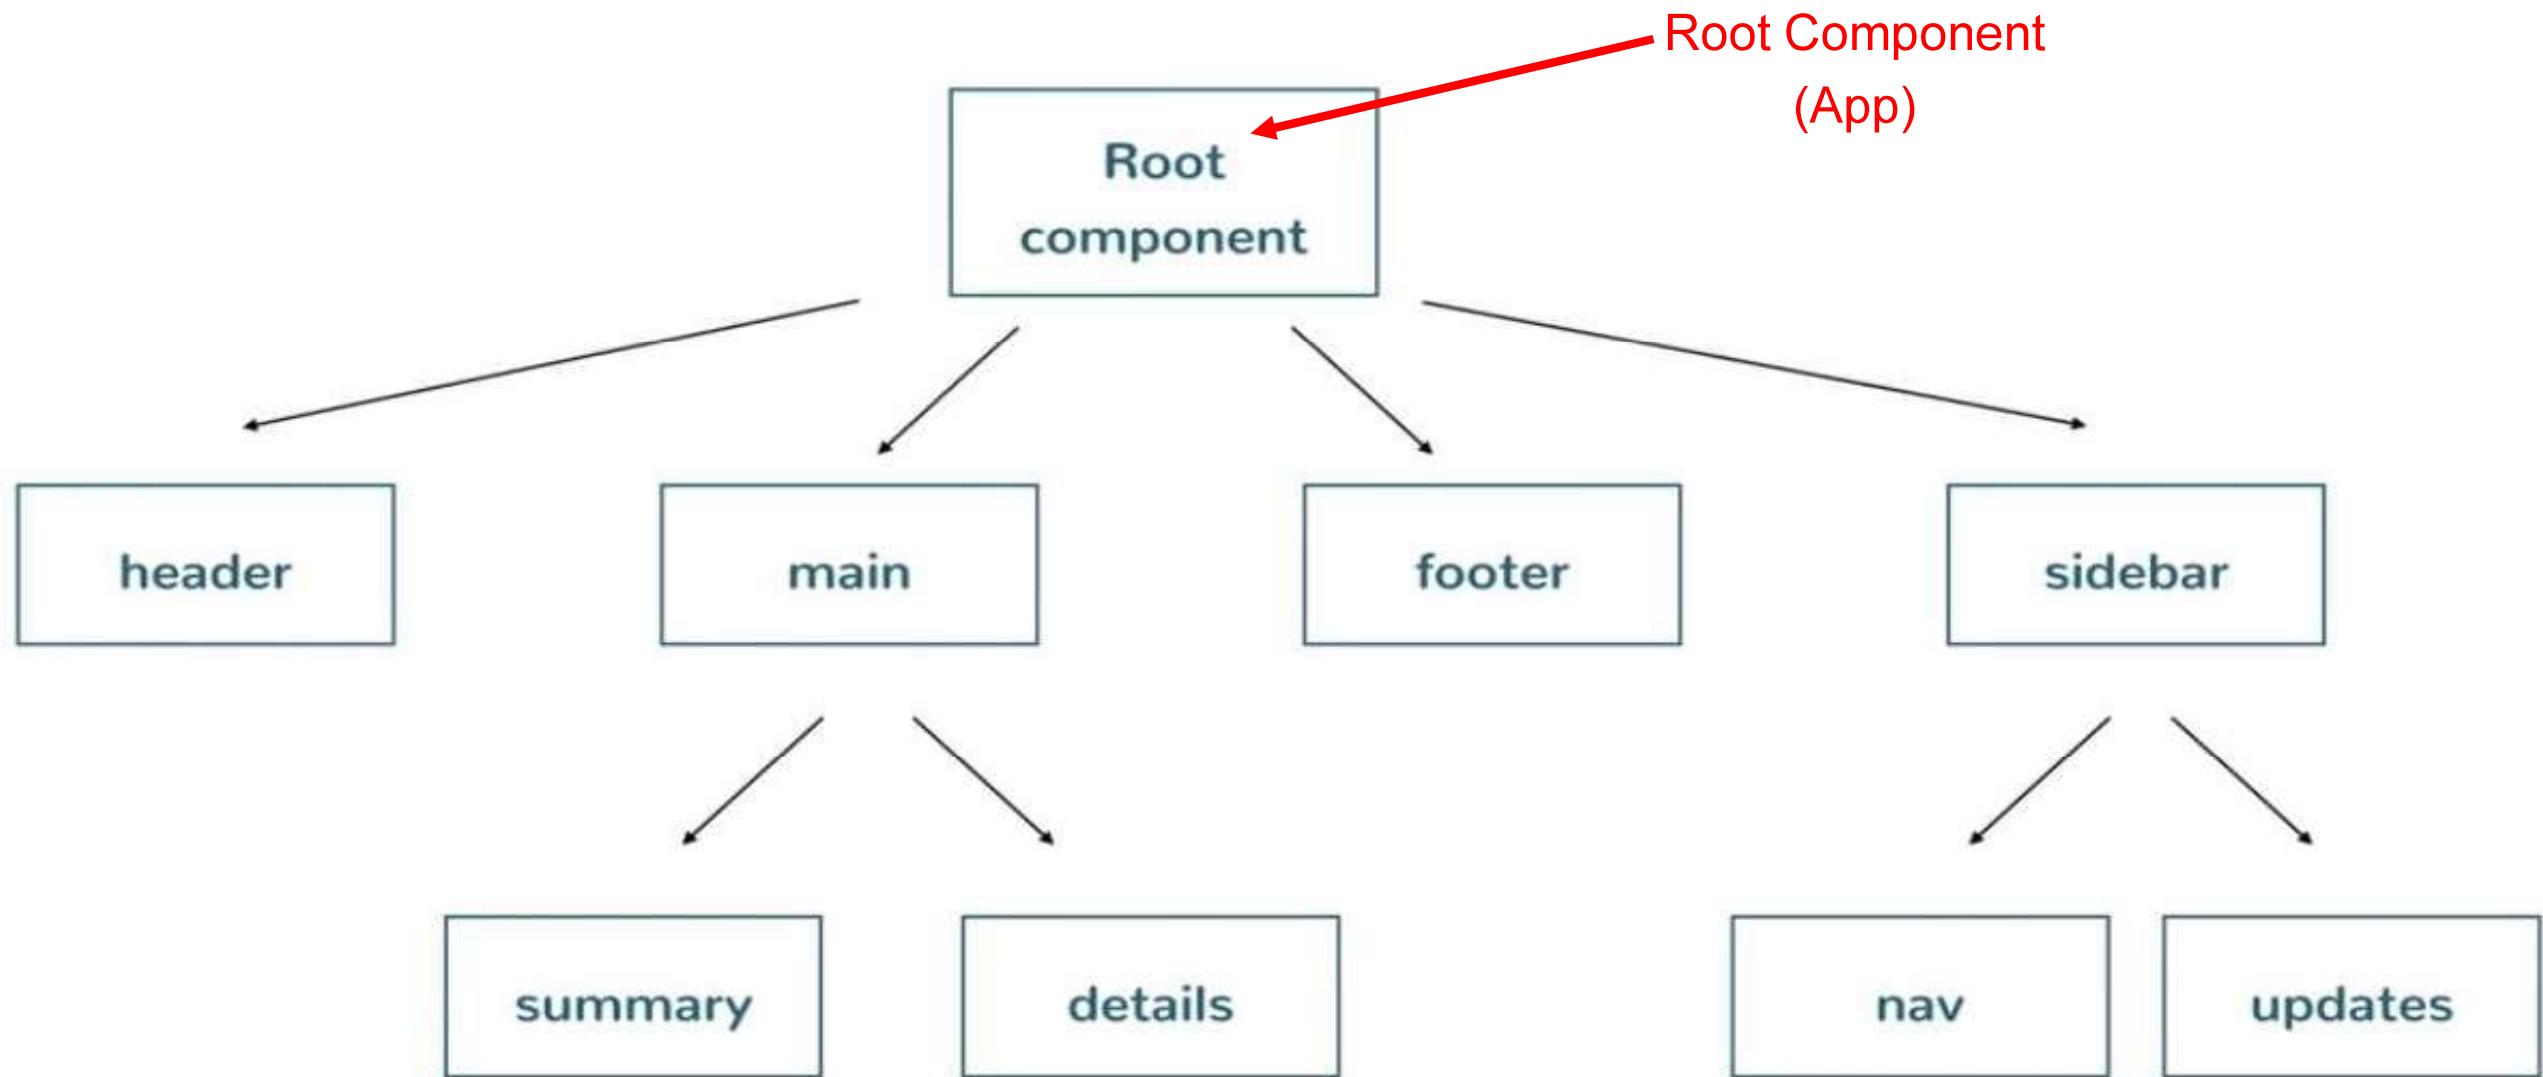

# Component Tree Structure

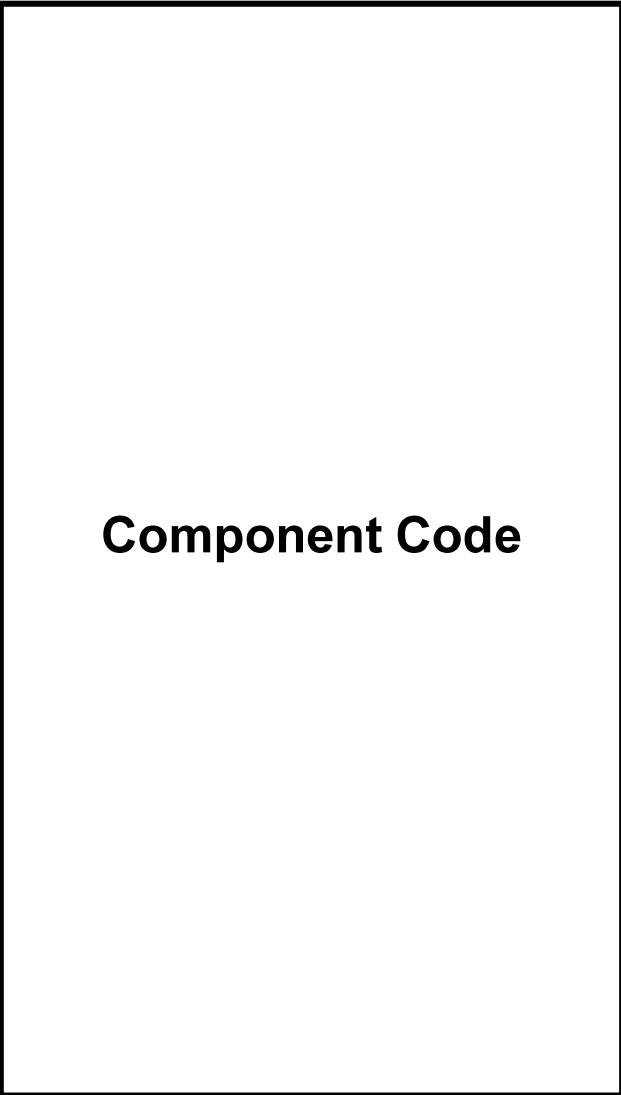

# Every React Application as a Root Component Which Holds Other Comps

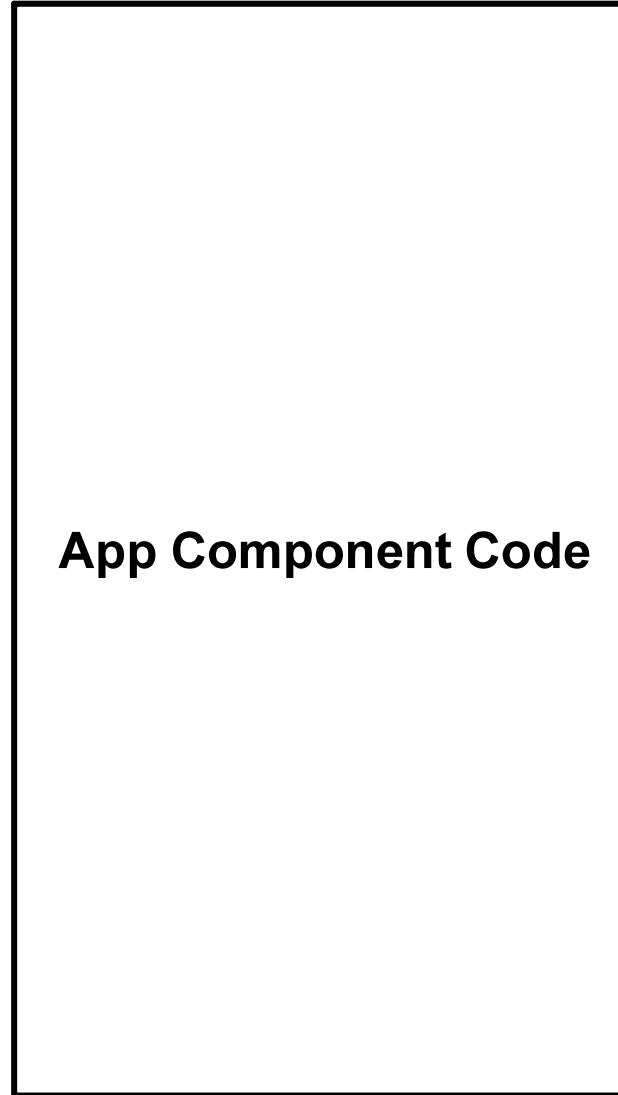

# Component in Code

JavaScript File

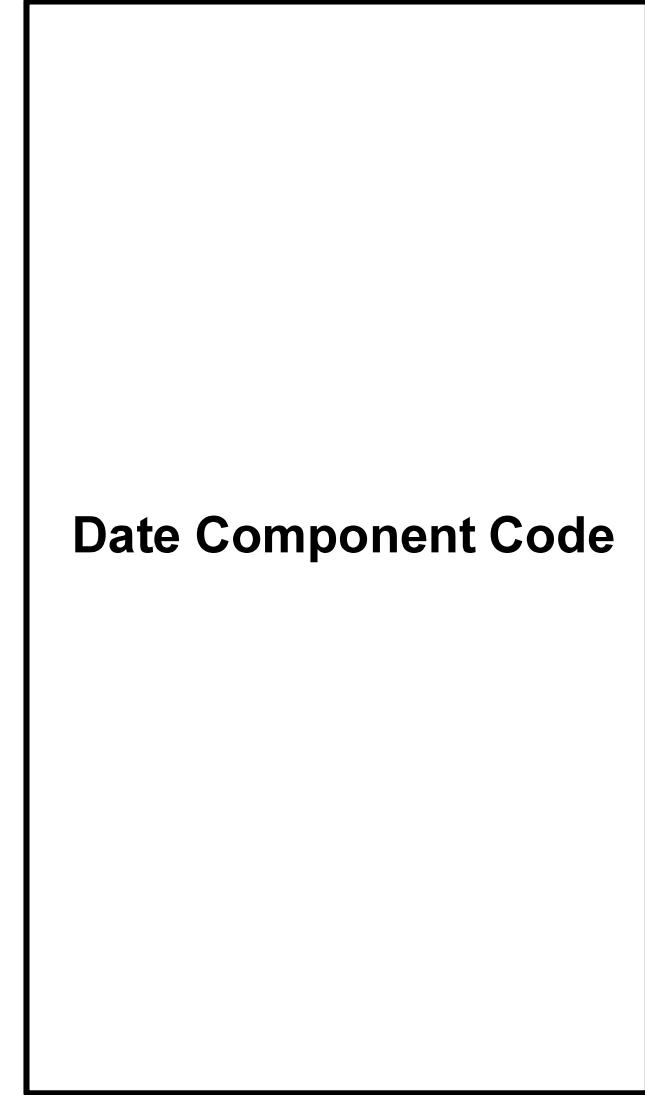

Component Code

App.js

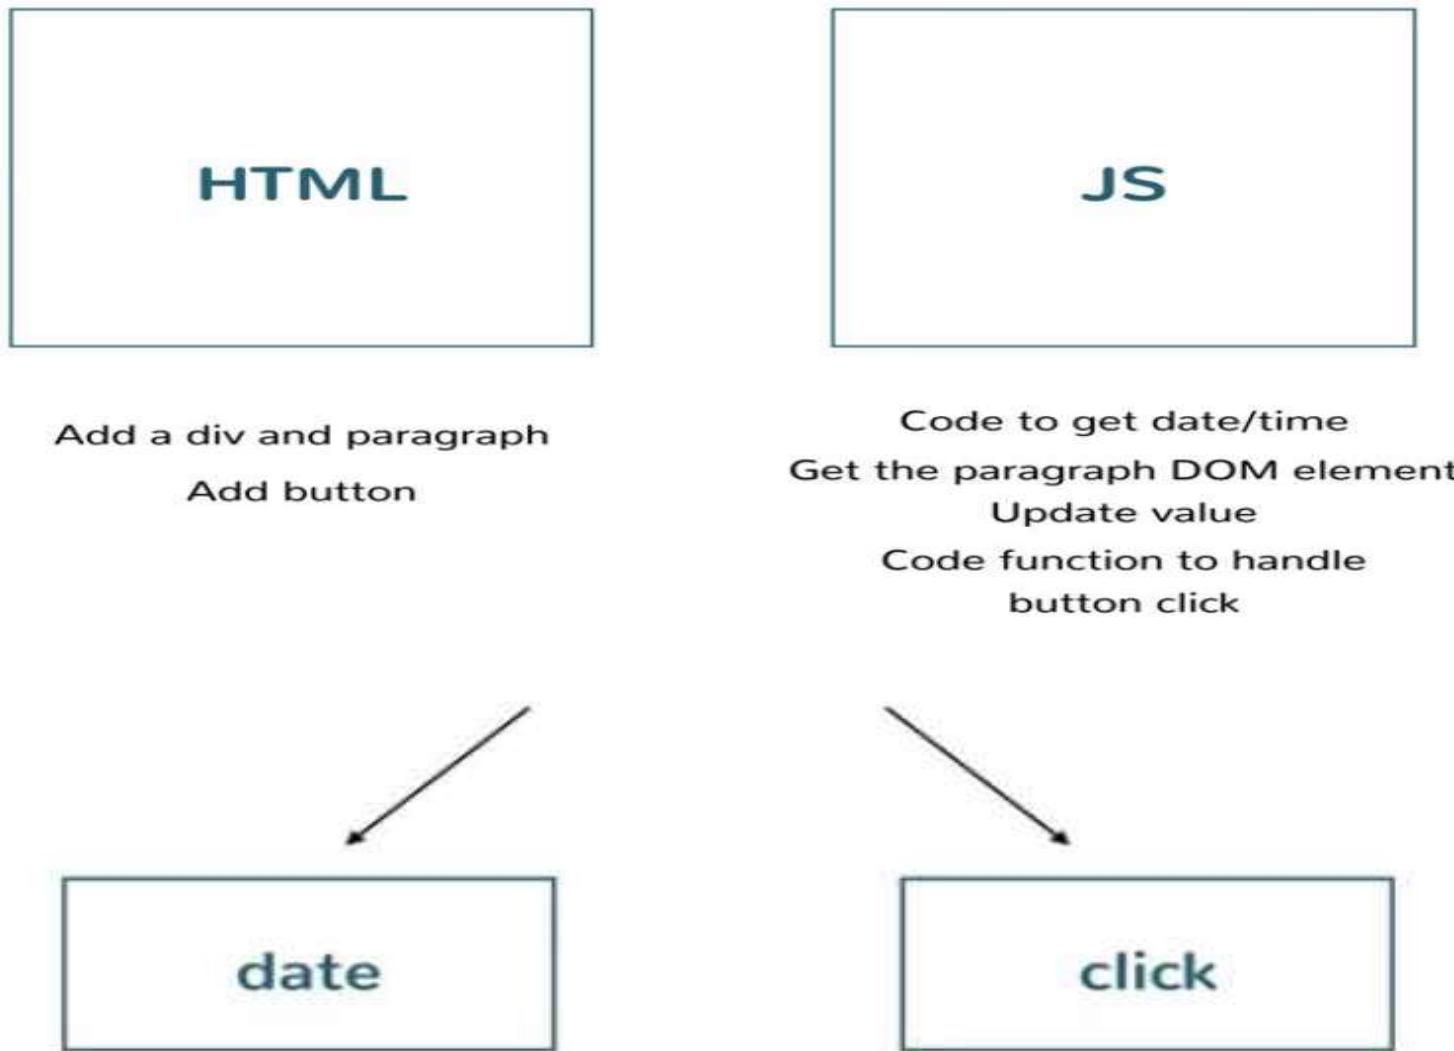

App Component Code

Date.js

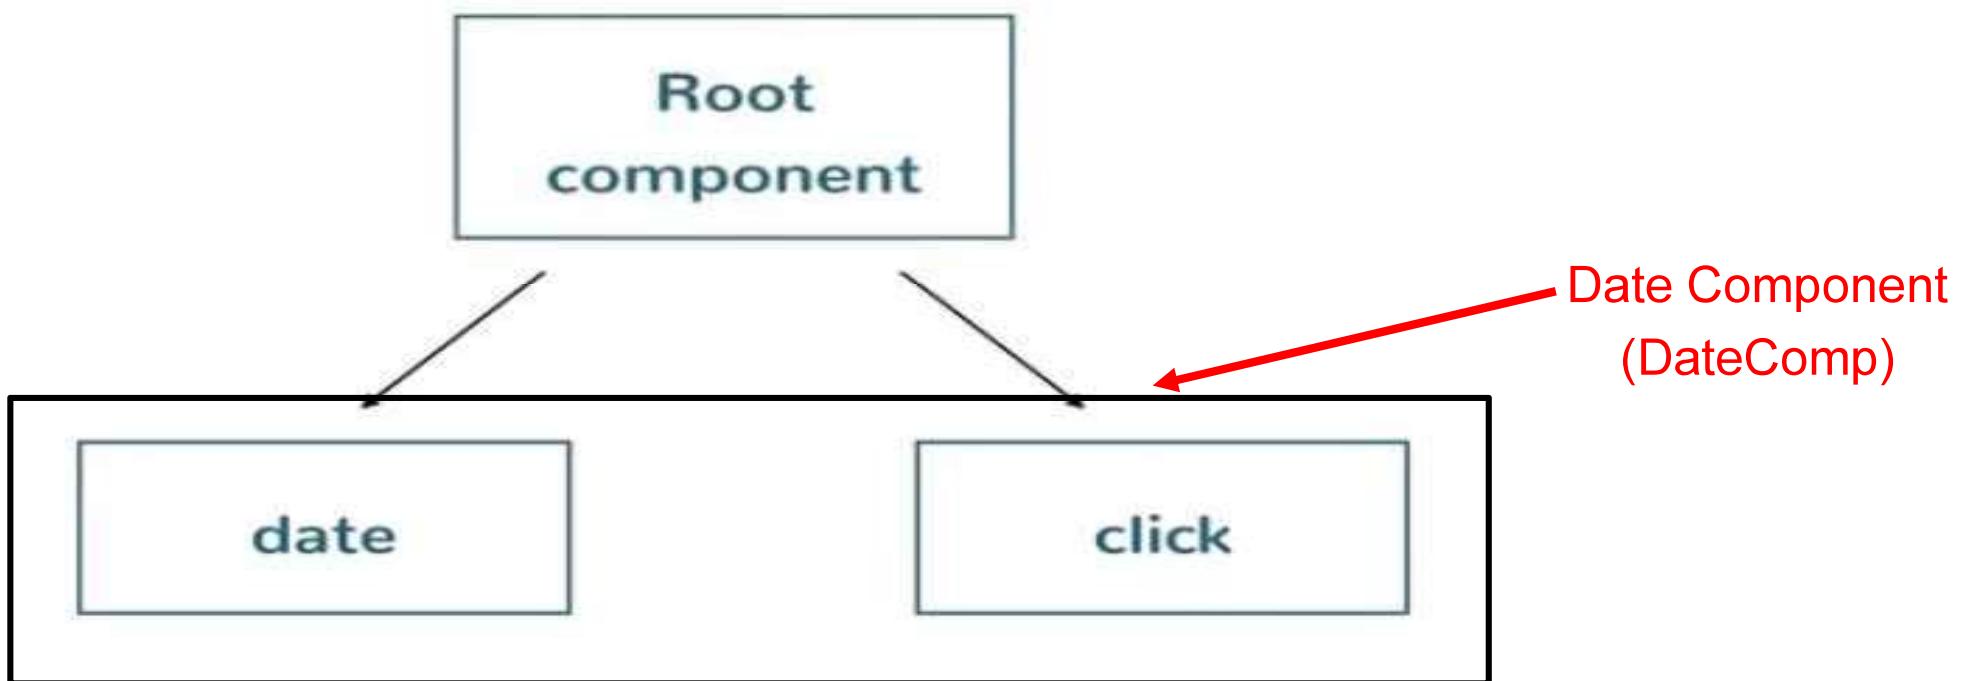

Date Component Code

# How it Alters Our Application

## Finally Our React Application Looks Like this

“In React, **everything** is a component”

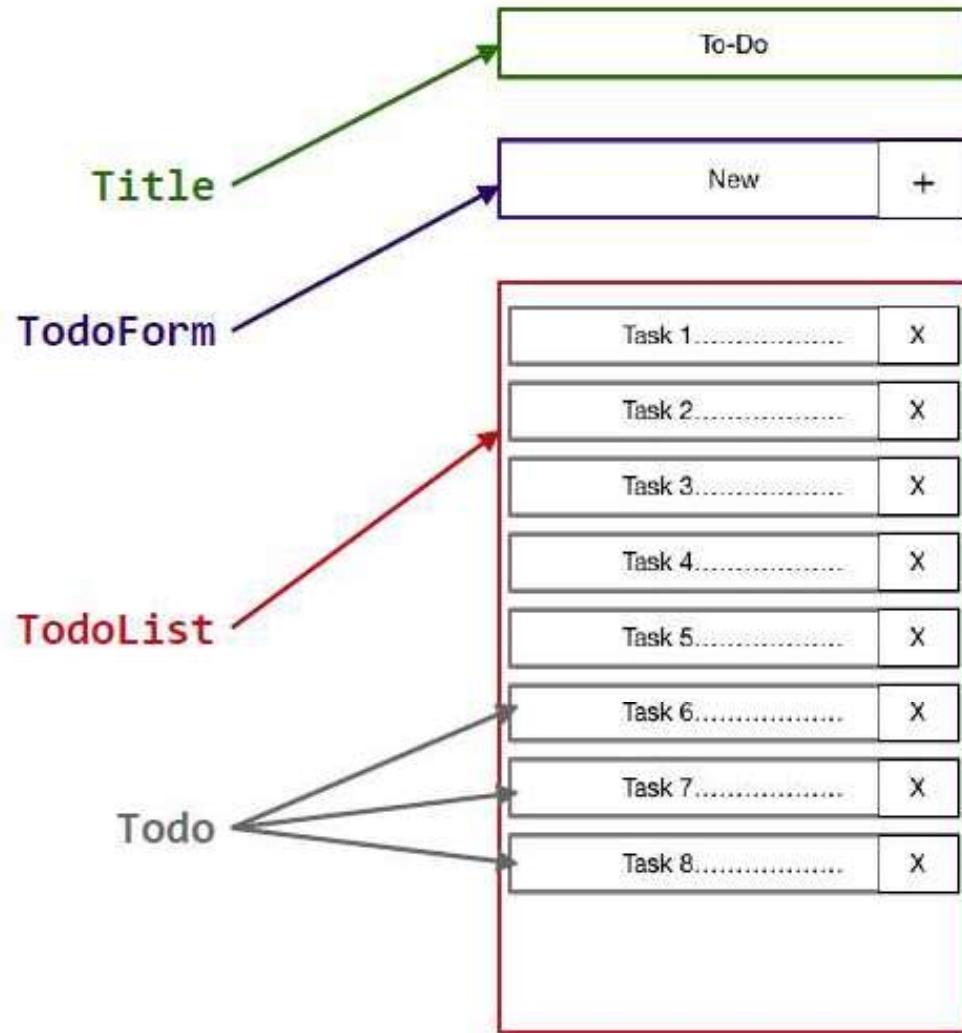

# Todo application

Big idea:

- A digital to-do list

First step:

- mockup / wireframe

# Creating a new React app

Creating a new React app is simple!

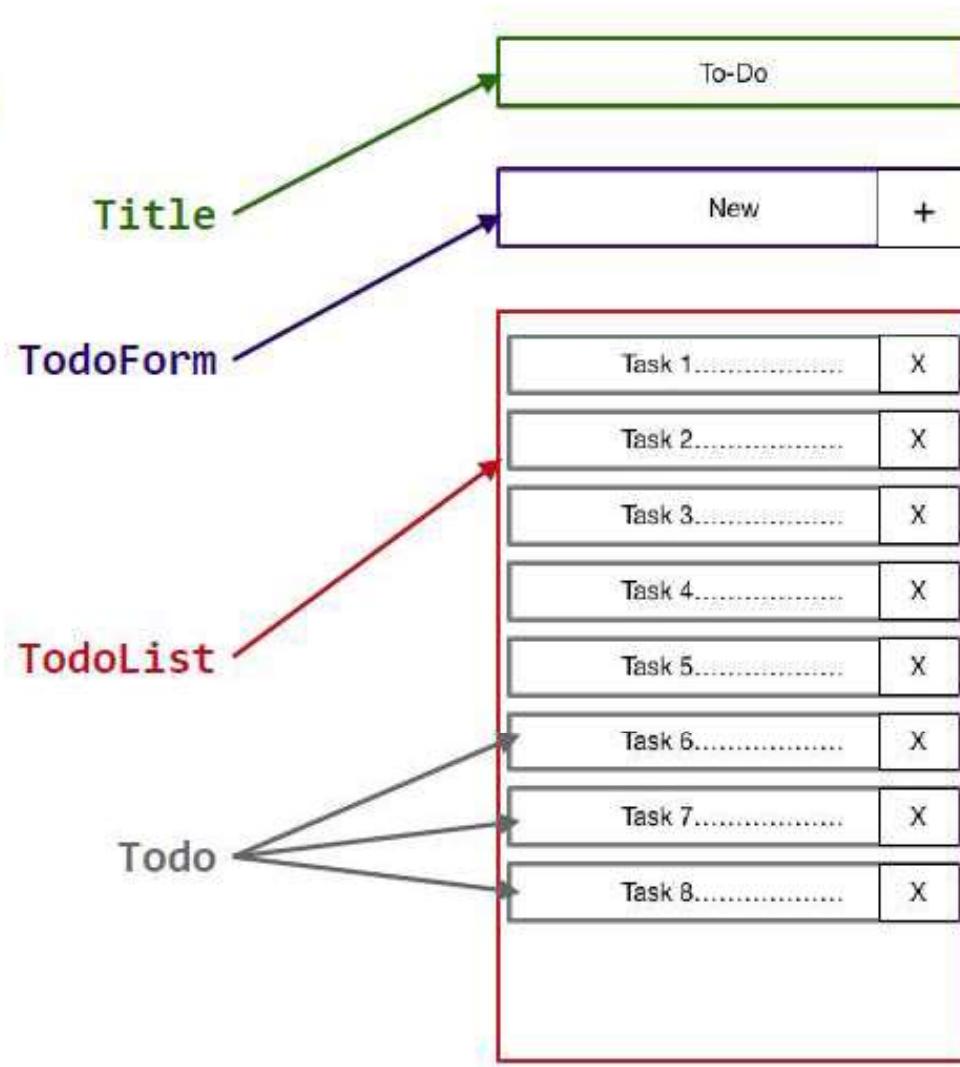

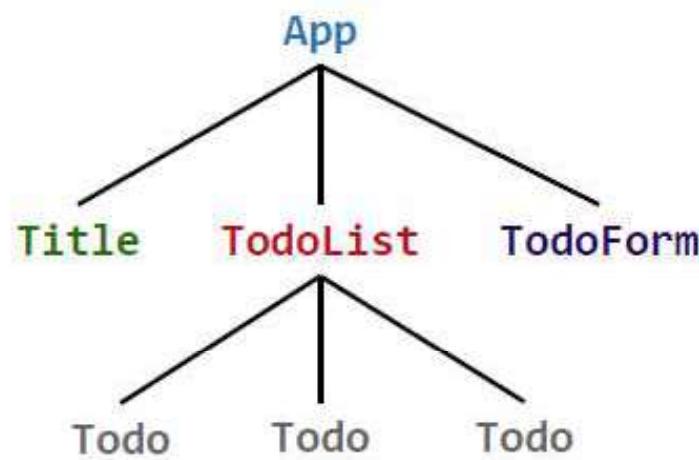

1. Install Node.js
2. Run: `npx create-react-app app-name`
3. New app created in folder: `./app-name`

# Anatomy of a new React app

## Anatomy of a new React app

# Component Hierarchy

## reactApp.js - Render element into browser DOM

```
import React from 'react';
import ReactDOM from 'react-dom';
import ReactAppView from './components/ReactAppView';

let viewTree = React.createElement(ReactAppView, null);
let where = document.getElementById('reactapp');

ReactDOM.render(viewTree, where);
```

ES6 Modules - Bring in React and web app React components.

Renders the tree of React elements (single component named **ReactAppView**) into the browser's DOM at the div with id=reactapp.

# Component Types

## Stateless Functional Component

### JavaScript Functions

```
function Welcome(props) {  
  return <h1> Welcome , {props.name} </h1>;  
}
```

## Stateful Class Component

### Class extending Component Class

```
class Welcome extends React.Component {  
  
  render() {  
    return <h1> Welcome , {this.props.name} </h1>;  
  }  
}
```

## components/ReactAppView.js - ES6 class definition

```
import React from 'react';

class ReactAppView extends React.Component {
  constructor(props) {
    super(props);
    ...
  }
  render() { ... }
}

export default ReactAppView;
```

Inherits from React.Component. props is set to the attributes passed to the component.

Require method render() - returns React element tree of the Component's view.

# ReactAppView render() method

```
render() {  
  let label = React.createElement('label', null, 'Name: ');  
  let input = React.createElement('input',  
    { type: 'text', value: this.state.yourName,  
      onChange: (event) => this.handleChange(event) });  
  let h1 = React.createElement('h1', null,  
    'Hello ', this.state.yourName, '!');  
  
  return React.createElement('div', null, label, input, h1);  
}
```

Returns element tree with div (label, input, and h1) elements

```
<div>  
  <label>Name: </label>  
  <input type="text" ... />  
  <h1>Hello {this.state.yourName}!</h1>  
</div>
```

Name:

Hello !

## ReactAppView render() method w/o variables

```
render() {
  return React.createElement('div', null,
    React.createElement('label', null, 'Name: '),
    React.createElement('input',
      { type: 'text', value: this.state.yourName,
        onChange: (event) => this.handleChange(event) }),
    React.createElement('h1', null,
      'Hello ', this.state.yourName, '!'))
}
```

# JSX templates must return a valid children param

- Templates can have JavaScript scope variables and expressions
  - `<div>{foo}</div>`
    - Valid if foo is in scope (i.e. if foo would have been a valid function call parameter)
  - `<div>{foo + 'S' + computeEndingString()}</div>`
    - Valid if foo & computeEndString in scope
- Template must evaluate to a value
  - `<div>if (useSpanish) { ... }</div>` - Doesn't work: if isn't an expression
  - Same problem with "for loops" and other JavaScript statements that don't return values
- Leads to contorted looking JSX: Example: Anonymous immediate functions
  - `<div>{ (function() { if ...; for ..; return val; })() }</div>`

# Use JSX to generate calls to createElement

```
render() {
  return (
    <div>
      <label>Name: </label>
      <input
        type="text"
        value={this.state.yourName}
        onChange={(event) => this.handleChange(event)}
      />
      <h1>Hello {this.state.yourName}!</h1>
    </div>
  );
}
```

- JSX makes building tree look like templated HTML embedded in JavaScript.

# Conditional render in JSX

- Use JavaScript Ternary operator (?:)

```
<div>{this.state.useSpanish ? <b>Hola</b> : "Hello"}</div>
```

- Use JavaScript variables

```
let greeting;
const en = "Hello"; const sp = <b>Hola</b>;
let {useSpanish} = this.prop;
if (useSpanish) {greeting = sp} else {greeting = en};

<div>{greeting}</div>
```

# Iteration in JSX

- Use JavaScript array variables

```
let listItems = [];
for (let i = 0; i < data.length; i++) {
  listItems.push(<li key={data[i]}>Data Value {data[i]}</li>);
}
return <ul>{listItems}</ul>;
```

- Functional programming

```
<ul>{data.map((d) => <li key={d}>Data Value {d}</li>)}</ul>
```

key= attribute improves efficiency of rendering on data change

# Styling with React/JSX - lots of different ways

```
import React from 'react';
import './ReactAppView.css';

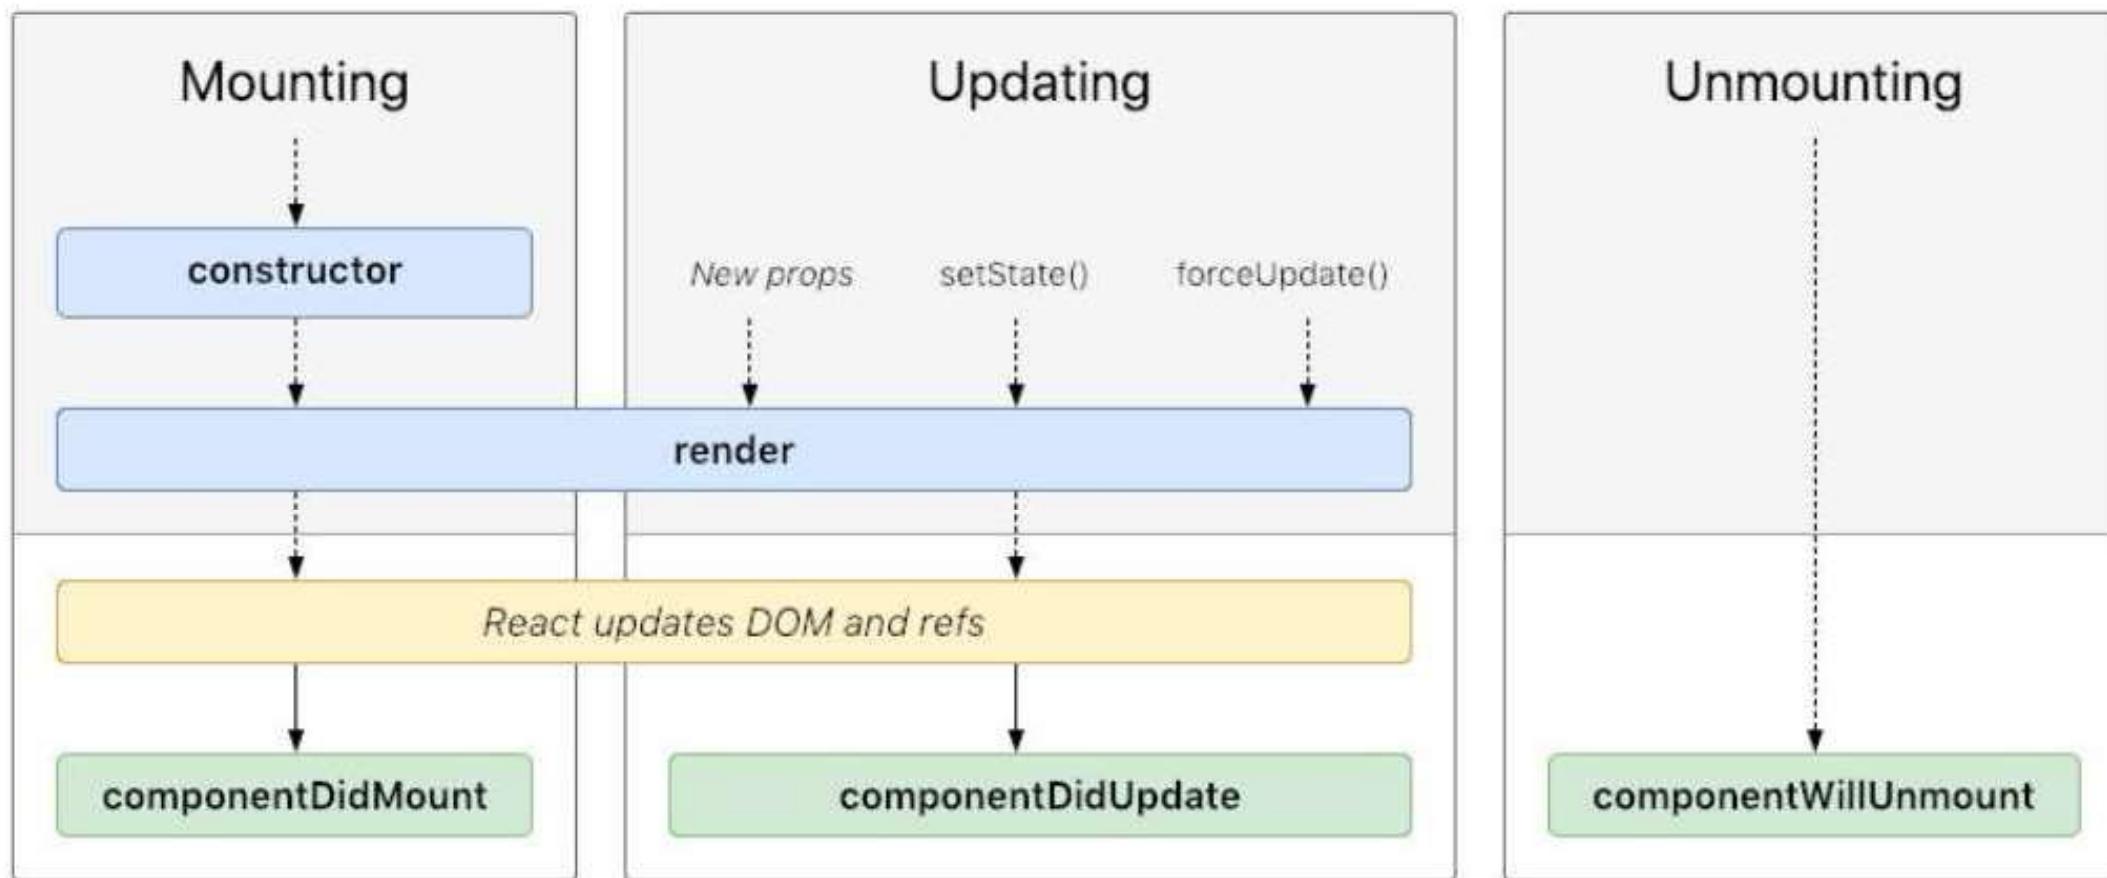

class ReactAppView extends React.Component {
  ...
  render() {
    return (
      <span className="cs142-code-name">
        ...
      </span>
    );
  }
}
```

Webpack can import CSS style sheets:

```
.cs142-code-name {
  font-family: Courier New, monospace;
}
```

Must use `className=` for HTML  
code= attribute (JS keyword conflict)

# Component lifecycle and methods

## Example of lifecycle methods - update UI every 2s

```
class Example extends React.Component {  
  ...  
  componentDidMount() { // Start 2 sec counter  
    const incFunc =  
      () => this.setState({ counter: this.state.counter + 1 });  
    this.timerID = setInterval(incFunc, 2 * 1000);  
  }  
  
  componentWillUnmount() { // Shutdown timer  
    clearInterval(this.timerID);  
  }  
  ...  
}
```

# Stateless Components

- React Component can be function (not a class) if it only depends on props

```
function MyComponent(props) {  
  return <div>My name is {props.name}</div>;  
}
```

Or using destructuring...

```
function MyComponent({name}) {  
  return <div>My name is {name}</div>;  
}
```

- Much more concise than a class with render method
  - But what if you have one bit of state...

# Component state and input handling

```
import React from 'react';

class ReactAppView extends React.Component {
  constructor(props) {
    super(props);
    this.state = {yourName: ""};
  }
  handleChange(event) {
    this.setState({ yourName: event.target.value });
  }
  ....
```

Make `<h1>Hello {this.state.yourName}!</h1>` work

- Input calls to `setState` which causes React to call `render()` again

## One way binding: Type 'D' Character in input box

- JSX statement: `<input type="text" value={this.state.yourName} onChange={(event) => this.handleChange(event)} />`  
Triggers `handleChange` call with `event.target.value == "D"`
- `handleChange - this.setState({yourName: event.target.value});`  
`this.state.yourName` is changed to "D"
  - React sees state change and calls render again:
  - Feature of React - highly efficient re-rendering

# Calling React Components from events: A problem

```
class ReactAppView extends React.Component {  
  ...  
  handleChange(event) {  
    this.setState({ yourName: event.target.value });  
  }  
  ...  
}
```

Understand why:

```
<input type="text" value={this.state.yourName} onChange={this.handleChange} />
```

Doesn't work!

# Calling React Components from events workaround

- Create instance function bound to instance

```
class ReactAppView extends React.Component {  
  constructor(props) {  
    super(props);  
    this.state = {yourName: ""};  
    this.handleChange = this.handleChange.bind(this);  
  }  
  handleChange(event) {  
    this.setState({ yourName: event.target.value });  
  }  
}
```

# Calling React Components from events workaround

- Using public fields of classes with arrow functions

```
class ReactAppView extends React.Component {  
  constructor(props) {  
    super(props);  
    this.state = {yourName: ""};  
  }  
  handleChange = (event) => {  
    this.setState({ yourName: event.target.value });  
  }  
  ...  
}
```

# Calling React Components from events workaround

- Using arrow functions in JSX

```
class ReactAppView extends React.Component {  
  ...  
  handleChange(event) {  
    this.setState({ yourName: event.target.value });  
  }  
  render() {  
    return (  
      <input type="text" value={this.state.yourName}  
        onChange={(event) => this.handleChange(event)} />  
    );  
  }  
}
```

## A digression: camelCase vs dash-case

Word separator in multiword variable name

- Use dashes: `active-buffer-entry`
- Capitalize first letter of each word: `activeBufferEntry`

Issue: HTML is case-insensitive but JavaScript is not.

ReactJS's JSX has HTML-like stuff embedded in JavaScript.

ReactJS: Use camelCase for attributes

AngularJS: Used both: dashes in HTML and camelCase in JavaScript!

## Special list **key** property

- **Situation:** Display a **dynamic array of elements**
- Must specify a special “**key**” property for each element
- The key of an item **uniquely identifies it**
- Used by React internally for **render optimization**
- Can be any unique value (string or number)

# What are **hooks**?

**Hooks:** Special functions that allow developers to hook into **state** and **lifecycle** of React components.

**State:** One or more data values associated with a React component instance.

**Lifecycle:** The events associated with a React component instance (create, render, destroy, etc).

Built-in hooks:

The diagram illustrates the built-in hooks in React. It shows two main groups of hooks, each enclosed in a curly brace. The first group, on the left, contains `useState` and `useEffect`. The second group, on the right, contains `useReducer`, `useMemo`, `useRef`, and `useCallback`.

{ `useState`  
  `useEffect`

{ `useReducer`  
  `useMemo`  
  `useRef`  
  `useCallback`

# React Hooks - Add state to stateless components

- Inside of a "stateless" component add state: `useState(initialStateValue)`
  - `useState` parameter: `initialStateValue` - the initial value of the state
  - `useState` return value: An two element polymorphic array
    - 0th element - The current value of the state
    - 1st element - A set function to call (like `this.setState`)
- Example: a bit of state:  
`const [bit, setBit] = useState(0);`
- How about lifecycle functions (e.g. `componentDidUpdate`, etc.)?
  - `useEffect(lifeCycleFunction, dependency array)`
    - `useEffect` parameter `lifeCycleFunction` - function to call when something changes

# First React hook: `useState`

Purpose:

1. Remember values internally when the component re-renders
2. Tell React to re-render the component when the value changes

Syntax:

```
const [val, setVal] = useState(100);
```

The current value

A setter function to  
change the value

The initial  
value to use

# React Hooks Example - useState

```
import React, { useState } from 'react';
function Example() {
  const [count, setCount] = useState(0);
  return (
    <div>
      <p>You clicked {count} times</p>
      <button onClick={() => setCount(count + 1)}>
        Click me
      </button>
    </div>
  );
}
```

# React Hooks Example - useEffect Model fetching

```
import React, { useState, useEffect } from 'react';
function Example() {
  const [count, setCount] = useState(0);
  const [fetch, setFetch] = useState(false);
  useEffect(() =>{setCount(modelFetch()); setFetch(true);}, [fetched]);
  return (
    <div>
      <p>You clicked {count} times</p>
      <button onClick={() => setCount(count + 1)}>
        Click me
      </button>
    </div>
  );
}
```

# Predicting component re-rendering

A component will only re-render when...

1. A value inside **props** changes

— or —

2. A **useState** setter is called

This means all data values displayed in the HTML should depend on either **props** or **useState**

## Second React hook: **useEffect**

Purpose:

Act as an **observer**, running code in response to value changes

Syntax:

```
useEffect(() => {  
  console.log(`myValue was changed! New value: ${myValue}`);  
}, [myValue]);
```

A list of values such that changes  
should trigger this code to run

The code to run when  
values change

# Communicating between React components

- Passing information from parent to child: Use props (attributes)

```
<ChildComponent param={infoForChildComponent} />
```

- Passing information from child to parent: Callbacks

```
this.parentCallback = (infoFromChild) =>  
  { /* processInfoFromChild */};
```

```
<ChildComponent callback={this.parentCallback}> />
```

- React Context (<https://reactjs.org/docs/context.html>)
  - Global variables for subtree of components

## Building a React project

- When you're ready to launch your app, run this command:

```
npm run build
```

- This bundles your app into CSS/JS/HTML files and puts them in the **/build** folder
- These files can be served from an AWS S3 bucket

## 3<sup>rd</sup> party components and libraries

- React-Router
- Redux
- Material-UI
- Bootstrap
- Font-Awesome
- SWR
